THE COLE

DIRECT-RETURN

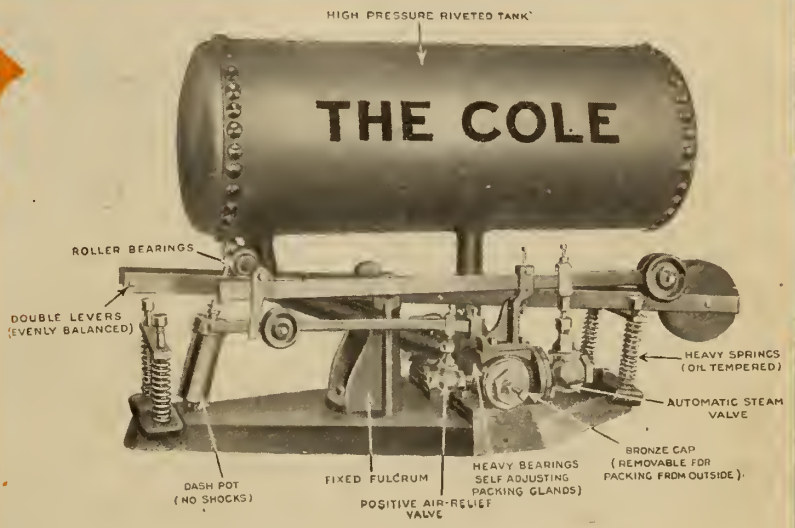
STEAM TRAP

for

LESS FUEL

and

MORE HEAT



ANY plant or building using steam should have Cole Equipment. It will save you money. Every year **Cole Steam Traps** are saving thousands of dollars in fuel for their users.

In any plant—no matter what the conditions are—**The Cole System** will deal effectively with condensation, returning it directly to the boiler, thus eliminating waste, and, as a result, effecting a large saving in fuel.

When buying be sure to specify **The Cole.** Our experience in Condensation Engineering extends over twenty years.

May one of our Engineers visit your plant, and study your problems? All applications of **The Cole System** are made with special reference to conditions which exist in each plant, for which the system is specified, hence success in every case.

Interesting literature upon request.

Even in Far Japan C-P Compressors are daily demonstrating their Success Qualities. These 3 Class O-CE units in the power plant of the Yokohama Dock Company, Yokohama, Japan, deliver 5,190 cubic feet of air per minute.

Success Qualities

SUCCESS QUALITIES that make good men make good air compressors. These qualities stand up under "hard knocks," stay on the job when they're needed, and *wear well* as the years speed on.

The *success qualities* of Chicago Pneumatic Air Compressors are these features, embodied in over three hundred sizes and types:

Simplate flat-disc indestructible valves, exceptionally large bearing surfaces, totally enclosed frame construction—

—automatic lubrication throughout, automatic regulation (insuring high operating economy under variable loads)—

—and unyielding, sturdy construction throughout, capable of withstanding *any* service condition.

Ask for Bulletins.

BOILERS

FOR POWER AND HEATING PURPOSES

You will find Waterous Horizontal Return Tabular Boilers in the largest industrial and municipal power plants in the country. There are reasons for this. They are economical of fuel, carry a big reserve steam pressure for use in emergencies, can be used with hard and dirty water, and are readily cleaned and easily taken care of. They cost little new; their upkeep and maintenance expense is negligible.

Waterous Horizontal Return Tubular Boilers are built in all sizes from 40 inches by 10 feet to 72 inches by 18 feet. Most standard sizes are carried in stock. If we cannot supply you at once from our yards we can turn out your order for you in quick time. On the next boiler you need let us quote you prices and delivery.

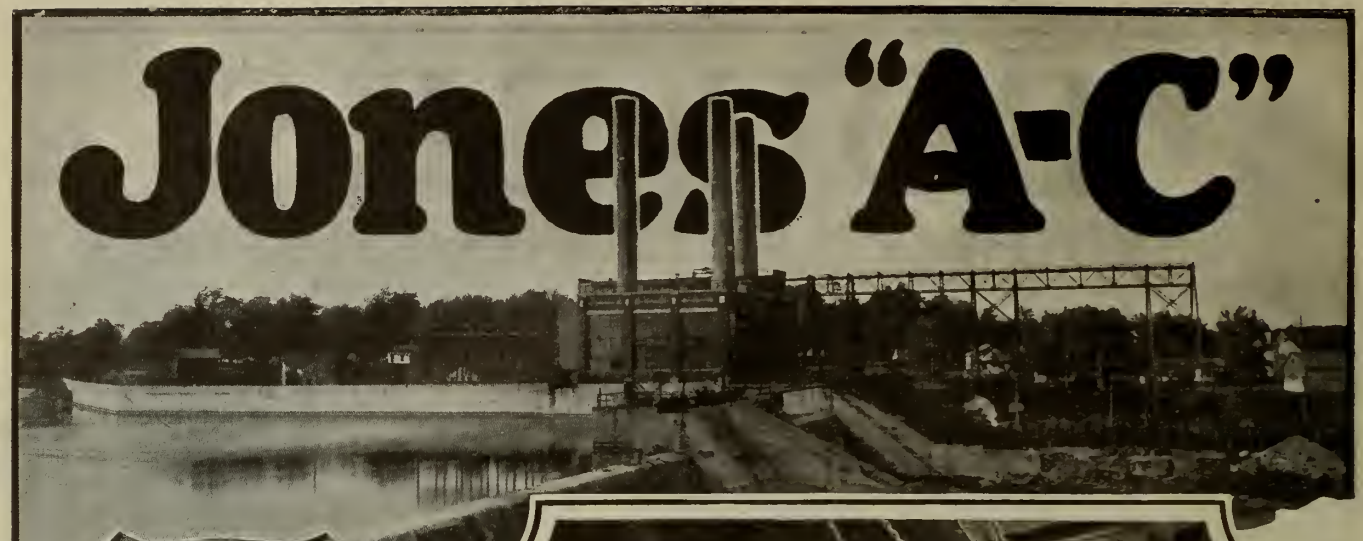
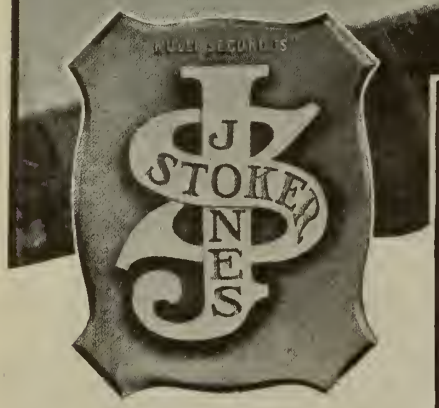
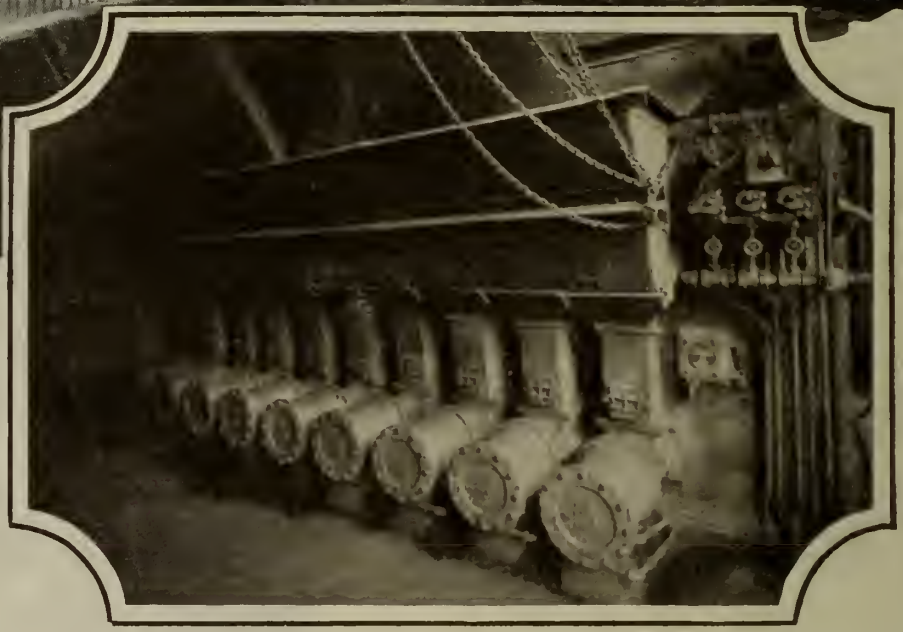
Jones "A-C"







Jones "A-C" Stokers used in connection with Hydro-Electric Development. The same stoker that is giving excellent results in large plants is also ideal for small plants. The saving is even more gratifying.

Since Hand Firing Won't Do . . . Install a Real High-Duty Stoker

TOO many stokers are merely substitutes for hand firing. By eliminating the waste of hand firing they effect economy—but not as great economy as is possible through real high-duty stoker firing. Small plants as well as large plants, to-day regard a stoker as a means of economy instead of an expense. First cost is considered only in relation to the dividend it yields.

The Jones "A-C" has proved its ability as a dividend producer by perfectly fulfilling the rigid requirements of high-duty stoking.

Its extreme simplicity—only one moving part, none in the fire—reduces maintenance and practically eliminates shut-downs.

The under-feed principle of combustion a principle originated in Jones stoker provides maximum combustion efficiency, ability to burn poor grades of coal, and heavy overload capacity.

The automatic-cleaning feature and special tuyere construction overcome objectionable formation of clinkers on front, side, and bridge walls.

Automatic control of fuel and air insures even steam pressure under widely varying load demands.

What single investment will yield as great return as high duty stoker firing?

The new Jones "A-C" Catalog explains this new coal and labor saver in detail. Ask for a copy.

THE UNDER-FEED STOKER CO. OF CANADA, LIMITED

81 VICTORIA STREET - TORONTO

Made in Canada for Canadians

The Jones "A-C" is 100% Canadian—made in Canada by Canadians, and sold for Canadian money at par. The former Jones Under-Feed Stoker Company, Ltd., an organization commanding great respect in Canada, has recently been replaced by the Under-Feed Stoker Company of Canada, Ltd. To the vast experience of the older company is added the engineering resources of the Under-Feed Stoker Company of America. This unrivalled engineering combination is at your command. Investigate.

Worthington satisfies every power plant pumping need

IMMENSE shop facilities, standardized manufacturing plus over 81 years of designing, improving and manufacturing pumps and pumping machinery have resulted in apparatus of suitable design for every power plant pumping duty.

This broad range and varied choice of apparatus together with over 200,000,000 boiler horse power successfully satisfied since 1840 justifies specifying Worthington for power plant apparatus. The Worthington engineering corps always stand ready to co-operate in order to obtain greatest possible results from apparatus selected.

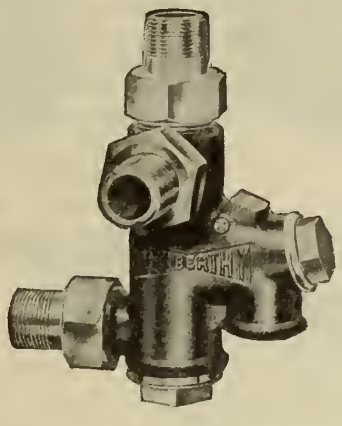
TRADE

PENBERTHY

MARK.



STANDARD OF THE WORLD!

On November 10th, 1918

The One Millionth

Penberthy Injector was completed and tested in the Penberthy shops and passed on its way to give the same efficient and satisfactory service that the other 999,999 that preceded it have given throughout the world.

What made this millionth Injector possible?

The Reputation for Reliability

That same trade mark is now associated with the highest grade line of brass valves on the market to-day. They are all designed with the "Outside bonnet construction," the first radical improvement made in brass valves in generations. They are made of the best quality of virgin metal, modern in design and of the best workmanship and finish. To get the most efficient and economical service

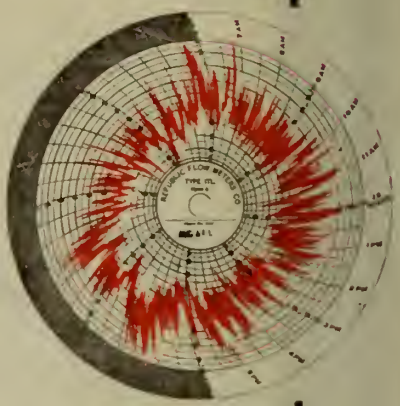
THE MASON TRADE-MARK

"SERVICE"

The charts on this page are from the plant of one of the largest Rubber Factories in Canada. In one of their processes it is absolutely necessary that steam be delivered at an even pressure, regardless of boiler pressure and the amount of steam used. The Mason Reducing Valve has been chosen to do this important service, as absolute reliability is essential—any variation of pressure, and therefore of temperature, meaning the loss of a day's production.

FIRST—THE BOILER PRESSURE

Fluctuating between
140 lbs. and 170 lbs.



SECOND—THE STEAM FLOW

Ranging from 100%, or full load
to only 10% of capacity.

THEN—A GENUINE MASON REDUCING VALVE

FINALLY—THE RESULT

an absolutely even pressure
—day and night—never varying a fraction of a pound.

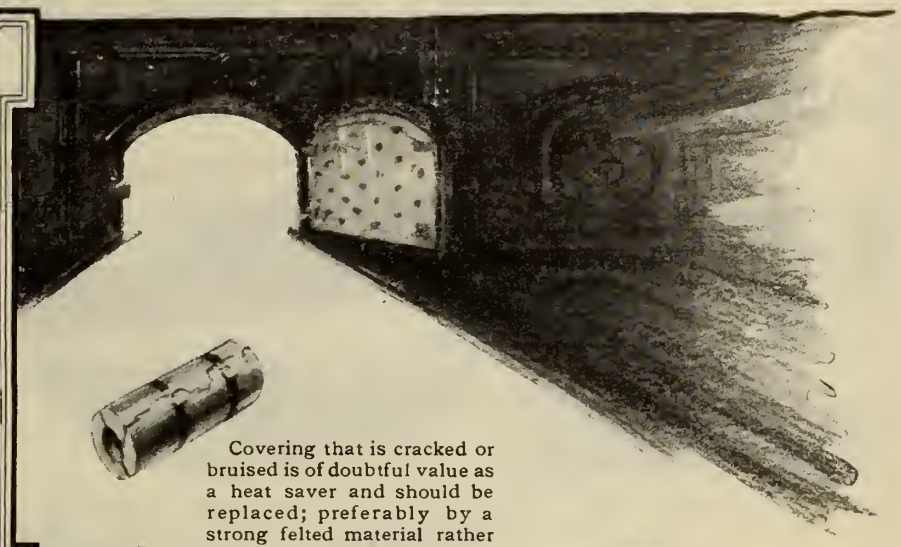
Six ways to tell how your heat is wasted

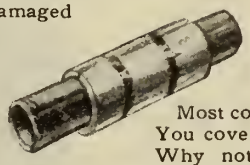
TO encourage fuel Saving we have thought it helpful to show some of the ways that heat is lost or wasted and how such losses can be located.

The common causes for heat loss are not deeply hidden. On the contrary, they are evident to anyone who will look for them.

If you find any one of the conditions below in your system, you can without a doubt be helped by Johns-Manville Insulation Service.

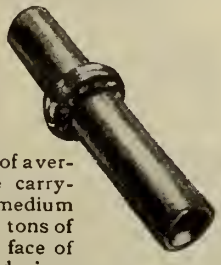


Covering that is cracked or bruised is of doubtful value as a heat saver and should be replaced; preferably by a strong felted material rather than the more easily damaged molded kind.

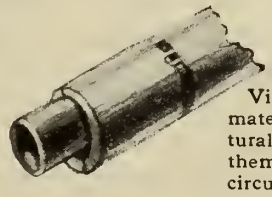


Most coverings are too thin. You cover pipes to save heat. Why not save all that is possible by using proper thickness—instead of accepting the partial saving of thin inadequate materials.

Often, pipes are covered but flanges and fittings left bare. Very wasteful. More fuel is wasted by leaving one pair of flanges bare than if a whole foot of the pipe itself were left uncovered.



Twenty-five feet of average size bare pipe carrying steam at a medium pressure wastes 14 tons of coal a year. In the face of this fact uncovered pipes are inexcusable.



Vibration wears away materials that are structurally weak causing them to sag, allowing circulation of air between covering and pipe, thus reducing their effective thickness and insulating value. Moral: Be sure that the material you use has more than heat-saving value—that it has long life as well—preferably a *felted* rather than a *molded* material.

Not only pipes but every hot surface must be insulated to secure maximum fuel savings. Don't be content with saving heat loss from pipes alone—find every hot surface and have it properly insulated.

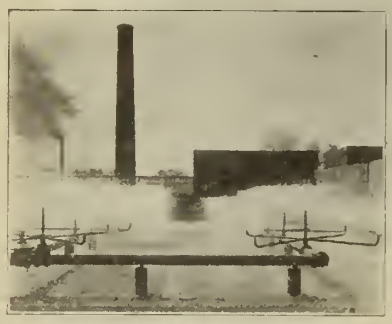
"SPRA-RITE"

Cooling Systems for Cooling Condenser Water



Iowa Railway & Light Co., Marshalltown.

Central Illinois Public Service Co., Harrisburg, Ill. Capacity 10,000 G.P.M.

Whitman & Barnes Mfg. Co., West Pullman, Ill.

"SPRA-RITE" The Modern Way

THE "SPRA-RITE" System is the modern means of water cooling where the plant is not within easy reach of natural bodies of water. This up-to-date method consists of Spray Cooling Ponds for cooling the condenser water so that the available supply can be used over and over again. The "SPRA-RITE" system meets every requirement in the shape of capacity, flexibility, and cooling efficiency. Spray ponds can be in any shape, depending upon the space available. Concrete ponds are extensively used; this is conceded to be the best practice. Natural ponds and specially constructed earthen basins may also be used with success. If ground space is limited a building roof may be utilized. We furnish plans and recommendation for any kind of installation.

SPRA-RITE Two-Vane Nozzle. Its function is to discharge fine spray of equal density throughout their entire cross section.

Its Benefits are Manifold

THE largest power and industrial plants of this and other countries are adopting Spray Cooling Ponds equipped with our well-known SPRA-RITE Nozzles and Cluster Fittings. Besides giving remarkable cooling capacity they frequently serve to reduce insurance rates as there is always ample water supply close at hand for use by fire pumps.

For Steam Condensing equipment SPRA-RITE Cooling Systems represent the highest standard of efficiency, but a spray cooling system will show its highest efficiency only when equipped with SPRA-RITE Nozzles, which were primarily designed for this application.

SPRA-RITE Cooling Systems have proved their efficiency for ice plant service. They are now considered standard equipment by refrigerating engineers and ice plant operators.

Let us have your inquiries regarding the cooling of water.

Two Degrees in Sixteen Hours

The single white line on this thermometer chart tells a more remarkable story than many lines of written words. The chart was taken in a pair of hardening rooms containing 3,000 gallons of cream in the plant of the American Ice Cream Co., Augusta, Ga., on July 21st and 22nd, 1920. At 8 P.M., the valve was closed and the machine shut down. At 3 A.M. and again at 8 A.M., employees entered the room to remove cream. At 12 noon, the room was opened, most of the cream removed, fresh cream put in and refrigeration again turned on.

Follow the line carefully and note that the two little jogs, when the room was opened, account for practically the total rise in temperature of **only two degrees in sixteen hours**, with the machine shut down. Remarkable as it is, this is not exceptional. It is typical of charts turned in daily at this plant.

Nothing but good design and **the best of insulation** make such records possible. In this case, eight inches of Nonpareil Corkboard on walls, floor and ceiling, stand between inside zero and outside summer so effectually that no refrigeration is required to hold a practically constant temperature for many hours. Such efficiency means profits on the balance sheet and dollars in the bank.

How to insulate for such results is explained in the 152-page book, "Nonpareil Corkboard Insulation"—thickness to use—how to erect it—complete information, fully detailed. There is no charge. Send for your copy.

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

The best bearing metal may come to grief through mechanical defects, which no babbitt could withstand, or by reason of faulty lubrication, as a grease that is too heavy for a light-running bearing, or an oil too thin for a heavy bearing, will invariably cause heating.

A highly fusible alloy rarely, if ever, gives timely warning before running out, whereas a Magnolia-lined bearing heats so slowly that it permits of either shutting down or cooling off the bearing, while running, without injury to shaft or bearing, and we shall recite cases where entire lack of lubrication has done no harm.

Tin is not the only metal that lowers the melting point of an alloy.

It is most natural to suppose that the melting point of a lead-antimony mixture would not be lower than lead, but that the addition of antimony would even make it higher. The eutectic of this series is 87 per cent. lead and 13 per cent. antimony and the melting point is 447° Fahrenheit, or 212° Fahrenheit less than the mean of the two metals.

It is a common practice to guarantee the melting point of babbit metals to be 600° Fahrenheit, and over, and to view this practice from a charitable standpoint, this guarantee is doubtless given because it is taken for granted that such ought to be the melting point. It is quite evident that the guarantors are not hampered by facts and have no definite knowledge upon which to base their assertions, but they run no risk of detection as buyers are just as much in the dark.

We have a Die-Casting Catalogue of recent date in which is given the melting point of their Genuine Babbitt as 810° Fahrenheit. We believe these figures were obtained from a college laboratory, which gives absolution from intentional misrepresentation, as it is highly improbable that such a wonderful alloy exists, but like many other babbitt manufacturers, they don't know any better.

I-C FLAT ARCHES

6 Reasons

1 This multi-piece bracket construction—a patented feature—made the building of LONG ARCHES possible and has blazed the trail in the development of modern furnace construction in which long arches are used exclusively. The bolted brackets hold the beams in alignment and absolutely maintain the unity of the structure which is designed to "stay put."

2 These cast iron brackets cannot warp or twist, and the high web carries the heat away from the bulb imbedded in the tile, thus prolonging the life of the bracket; however, any section can be removed or repaired, without disturbing the balance of the structure.

3 Heavy brackets on the extremities of the cross beams rest on and spread the weight over the side walls. All expansion is taken care of within the arch itself and there is absolutely no side thrust on the furnace walls.

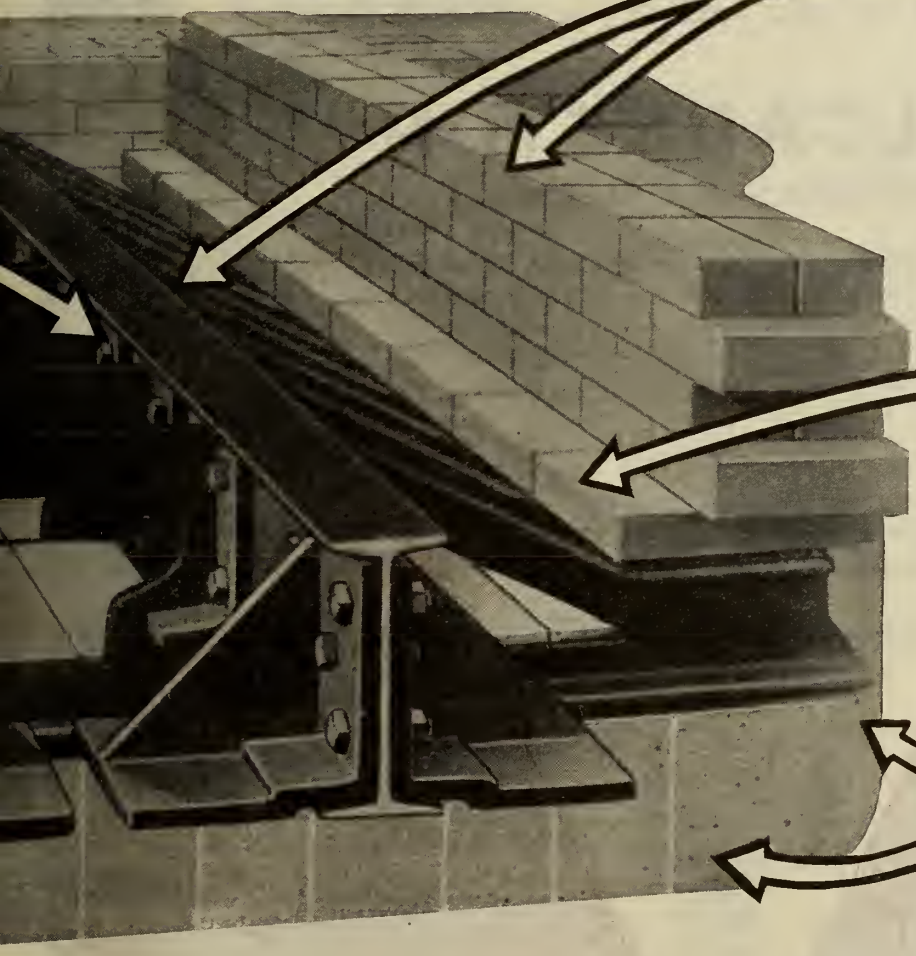
IN STOCK

LACLEDE

A BUSINESS INSTITUTION

FOR BOILER AND METALLURGICAL FURNACES

For Superiority



4 The bracketed cantilever construction carries the Arch well out past the last cross beam, so that perfect ventilation is obtained between the curtain wall and this beam, as well as around all the rest of the ironwork.

5 The curtain wall is supported by flat tile resting on the brackets, and is absolutely independent of the Arch Tile. The Arch Tile can be removed or replaced without disturbing the curtain wall.

6 Note the exceptional depth and the plain shape of the tile. This tile is of the highest grade materials, and is furnished in either the side hung, or the center hung design.

REALLY Troubleproof and Economical

The Bronze Face and Seat prevent deterioration and loosening up in service.

Manufactured by Dart Union Co., Limited, Toronto, Canada

This is the Vulcan method of cleaning boilers of the Stirling Steep Tube Type—BETWEEN THE TUBES.

Why CLEAN Boilers Burn Less Fuel

All boiler manufacturers agree on and emphasize the fact that their boilers burn fuel most efficiently and economically when the furnace fire and water in the tubes are permitted to come into contact with each other with a minimum of interference. Thus, boilers whose tubes are kept free from soot, ash and scale accumulations consume less fuel in order to maintain a given steam pressure than boilers which are regularly neglected, or only partially cleaned.

Vulcan Soot Cleaners assure thorough cleanliness so far as the soot and ash are concerned. They are responsible, in most plants where used, for saving between 4 per cent. and 8 per cent. of the fuel consumption, or for reducing the preventable losses 20 per cent. to as high as 40 per cent.

While you're thinking of it, write and ask for the interesting folder, "SPENDING $796 TO SAVE $1,017.40!"

Vulcan Soot Cleaners are manufactured for all types of water tube and return tubular boilers, superheaters and economizers. For quotations, write to either Canadian office, giving type of boiler, number of tubes wide and high, and steam pressure.

This is the famous Vulcan diagonal method of blowing as used in boilers of the staggered tube type—B&W, Goldie & McCulloch, etc.

Oil Fuel From the Well to the Consumer*

The Stratification and Processes of Distillation of Crude Oil are Explained, and a Number of Applications of Oil Fuel Burners To Furnaces With Natural and Forced Draught are Given.

By J. H. WILLIAMS

NATURE has hidden in the earth and in the waters under the earth many things useful to man, but there are few, if any, more useful to man than oil, and the term "struck oil" has become familiar as an expression for having acquired riches.

Origin.—The origin of petroleum is not known with any certainty, but a widely held theory is that it was formed during the carboniferous periods of the world's history by the decomposition and destructive distillation of the vast marine vegetation and animal organisms then existing, much in the same way that the coal measures were formed from terrestrial vegetation. Formerly much more of the world's surface was covered by water than at present and there were many shallow seas or swamps where the slowly rotting marine growths were deposited with sedimentary sands and calcareous matter of marine organisms, and as ages passed these deposits were covered over and sealed in. Under the effect of heat and pressure through a long period of time these organic deposits were decomposed and formed liquid petroleum and gas, and remained in the porous strata of sand and lime until the present day. It would appear that such deposits should naturally be horizontal, but during the cooling of the earth's surface volcanic movements have occurred, and probably due to contraction, have resulted in wave-like formations or curves presenting the appearance of low rolling hills and valleys. Petroleum is usually found where the earth's movements have not been of a very violent nature.

Referring to Fig. 1 the cap of the curve is termed the "Anticline" and the hollow the "Syncline." The well is usually drilled in the slope of the anticline in order that the greatest amount of oil can be drawn off in the most economical manner. Salt water is nearly always found in petroleum wells and being heavier than oil is found in the lower part of the anticline or in the syncline, while the gas, if there is any, collects under the cap. The pressure of the gas forces the oil up the casing and saves the cost of pumping.

Locating a position for an oil well is not as simple as it may sound, even when the presence of oil is suspected in a district. The most common surface indications are "seepages" or leakage of oil to the surface from its underground source. Seepages are fequently deceptive because the subterranean pool may be a considerable distance horizontally, sometimes miles, from the surface position of the seepage.

In Fig. 1 the strata are shown running parallel to the surface and parallel to each other, it is quite easy to imagine that the strata do not always arrange themselves in such an orderly manner. In the case of a fault as shown by diagram Fig. 2 the oil would probably leak from the oil sand under gas pressure and travel under the overlying impervious strata of clay and limestone until it met a pervious formation through which it could filter up to the surface.

Locating a well is not an exact science but is generally the result of much labor and thought on the part of expert geologists.

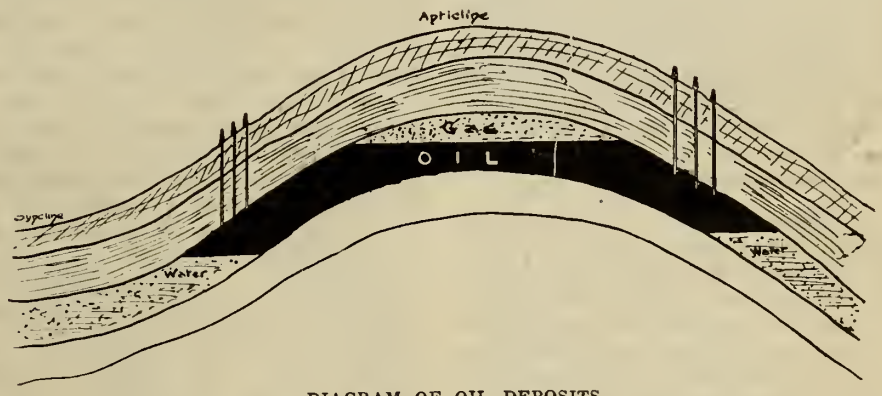

DIAGRAM OF OIL DEPOSITS.

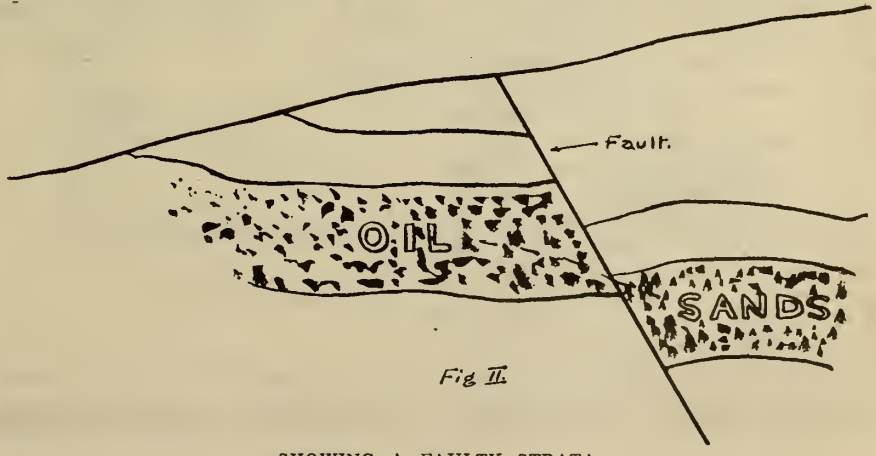
Winning Oil.—Drilling operations. Petroleum wells are drilled in a somewhat similar manner to drilling for water.

The outfit is generally referred to as the "Rig" and the type of "Rig" to be adopted is determined by local conditions and the strata through which the bore passes.



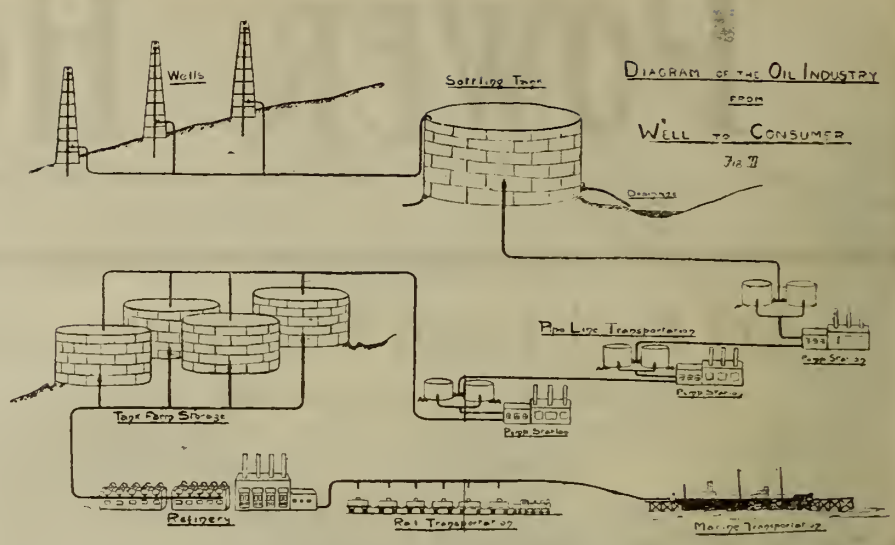
SHOWING A FAULTY STRATA.

*Transactions of the Institute of Marine Engineers.

There are two systems of drilling: (1) The standard or percussion system. (2) The rotary system.

First a hole is dug, and over the hole a derrick is erected about 80 feet in height and 24 feet square at the base. This derrick has to support the well casing and the string of tools. Drilling is more rapid with the rotary system than with the percussion up to about 2,000 feet depth, at which point there is very little difference in the rate. The standard system has some advantages of its own, depending upon the formation passed through, in the hardest formations the well will more nearly approach the vertical. In the standard rig there are two pulleys on the top of the derrick, one carrying the cable with the string of tools, and the other carrying a rope with the bailer. The rope carrying the tools is fixed to one end of a beam or lever called the walking beam, and the other end of the beam is operated by a steam engine. (Before any oil is discovered the boiler is fired by wood cut from the bush around and if the well is not a "dry hole" it is subsequently "oil fired"). This gives the necessary motion to the tools. The drill stem or bit is operated for a certain number of hours, according to the nature of the strata through which the boring is passing when it is taken off to be "dressed" or sharpened, and while this tool is being changed the bailer is connected up and the water and borings made by the drill are pumped out. This operation proceeds night and day.

All wells require to be cased to prevent the sides caving in, and to prevent the infiltration of water. In Mexico casing usually starts with a 14-in. or 12-in. steel pipe and finishes up with a 6-in. or 4-in. pipe. The casing follows the drill, thus while the string of tools works in the casing the point of the drill is always ahead of the casing. The rotary system is mainly used for sinking deep wells through loose or soft formations. The operation consists in rapidly turning a column of pipe at the end of which is a special tool for cutting the formation through which it is passing. To wash out the cuttings, and so leave a clear surface for the cutter to work upon, water is forced through the pipe under such pressure as to cause it to return to the surface on the outside of the pipe. By this means a column of pipe can easily be sunk through beds of sand, gravel or other soft formation which otherwise through their lack of stability would render it very difficult to first drill a hole and then insert the pipe or casing to form the wall of the well as in the percussion system. It takes anything from 60 days to 300 days to drill a well, the rate of drilling being much retarded where there are serious water troubles, or beds of hard rock. Wells vary in depth from 500 ft. to 4,000 ft., generally the deeper wells produce the lighter gravity oils. The oil bearing strata or producing sands vary from 200 ft. to 500 ft. in depth.



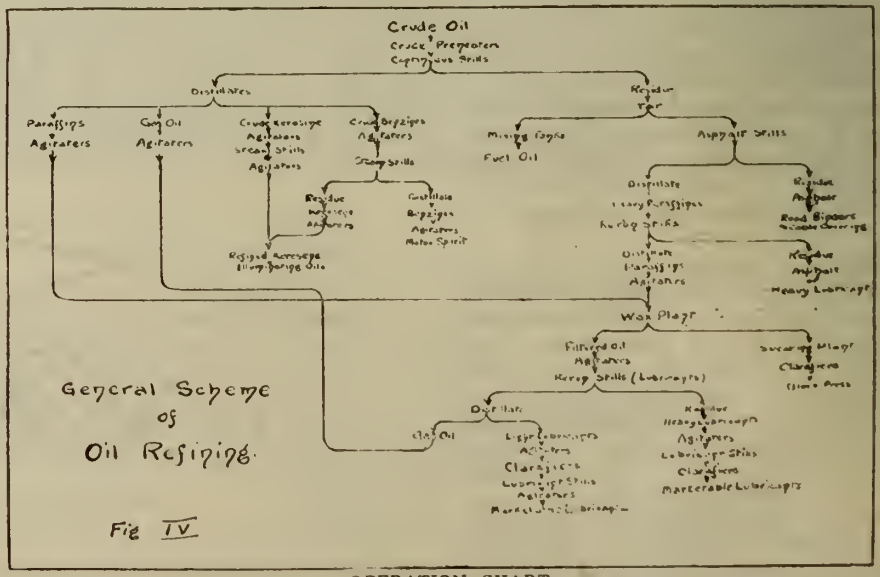
FROM WELL TO CONSUMER.

Some years ago particulars were given in an American publication of the cost of completing an oil well in California. It was then stated to be anywhere from £2,000 to £20,000, depending, of course, upon the strata through which the well is drilled. In a proved oil country the estimate was £2 to £3 per foot. When exploring new fields, of course, the cost of every "dry hole" must be added to the cost of the producing wells; from this it will be easy to see why oil is not exactly given away, especially when for every producing well two "dry holes" are bored, and it has been stated that for all the producing wells about 70 per cent. yield less than 100 barrels per day (about 14 tons).

Storage.—The crude oil when first brought to the surface is found to contain water and dirt, generally sand, and is of a dark brown or black color, and is very rarely a light color or transparent. From the well the oil is run or pumped into a preliminary storage tank, where the sand and water are allowed to settle out before the oil is transported to the refinery. Fig. 3 illustrates diagrammatically the progress of the oil from well to consumer.

Light oils are refined as soon as possible to avoid evaporation of the volatile constituents. Heavy oils can be stored for a considerable time without great loss. Steel tanks are usually employed for storage of oil, but heavy oils can be stored in clay or earth reservoirs covered with a wooden roof. This is a very cheap method of storage, but is not highly recommended because the walls of the reservoir have been known to be washed away when a heavy rainfall occurred.

Transportation. Land and Ocean.—The value of oil depends upon its availability. Inaccessible fields require pipe lines of great length. The location for a pipe line is determined by the topography of the district through which the line passes, in much the same way as a railway line; it is obviously not advisable to carry a pipe line over a mountain or through a lake if it can be avoided. Main pipe lines are generally 8 in. diameter, the tendency being to increase the diameter for the heavier and more viscous oils.



OPERATION CHART.

The 8-in. pipe weighs 28 lbs. per foot, and has a cubic capacity of 47 tons per mile. The principal factors in transportation of oil, either by pipe line or ship, are its physical characteristics as

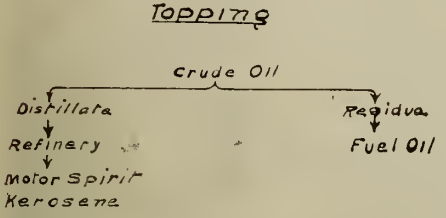


FIG. 5.

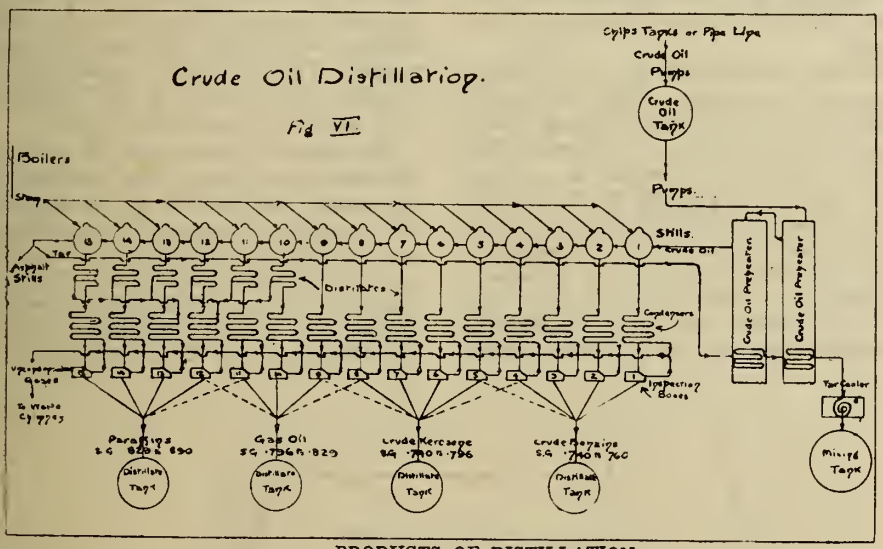
regards gravity and viscosity (otherwise its weight and resistance to pumping). The method adopted to overcome the difficulty is to heat the oil to a temperature of about 120 degs. Fah. depending upon the nature of the oil.* High temperatures cause gasification, and give trouble at the pumps, the heating therefore should be carried out on the delivery side of the pump. The capacity of a pipe line is determined by the working pressure at the pumps, the viscosity of the oil (which is due to composition and temperature), and the climatic conditions (temperature and rainfall) and the distance between the pump stations. The capacity of a pipe for oil increases faster than the square of the diameter because the friction decreases with increase of size. A pipe line consists of: 1, Field station; 2, Intermediate stations. 3, Terminal station.

The field station consists of a large number of storage tanks, two or more horizontal duplex pumps, with the necessary boilers, condensers, feed and circulating pumps, electric lighting and exhaust steam heaters for heating the oil preparatory to pumping it to the first of what we will call intermediate stations. The intermediate stations are very much like the field stations, but there is less equipment, only two storage tanks being necessary and they are usually of smaller capacity than on the field or terminal stations. While one tank is receiving the oil from the preceding station, the oil is being pumped from the second tank on to the following station on the line. The terminal station consists of from 20 to 50 storage tanks and the pumps are constructed for a lower pressure, the duty being to deliver the oil into the refinery or to tank steamers for export. The pumps are duplex, triple or compound, depending upon the supply of fresh water available at the station, if good boiler water is not available triple expansion pumps are installed with ample evaporators.

Through an 8-in. line, 32 miles long, from Potrero to Tuxpam, 5,000 tons per day are pumped. There is one field station, two intermediate stations, and the receiving station at Tuxpam. The latter is situated on the coast of the Gulf of Mexico at the mouth of the Tuxpam River, but as there are only five feet of water on the bar the ships lie one mile off the shore and pipe lines are laid on the sea bed with a flexible hose at the sea end, and here the ships are loaded without entering port. Another 8-in. pipe line runs from Potrero to Tampico Refinery, a distance of 100 miles. On this line there are 8 pump stations, and 3,500 tons per day are pumped to the refinery at a pressure of 600 to 800 lbs. per square inch. We have now brought the oil to the refinery.



PRODUCTS OF DISTILLATION

Refining.—The question is frequently asked, "What is petroleum?" The chemist will tell you that it is saturated hydrocarbons and then we are not much wiser. So far the chemist has only touched the fringe of the subject, there is every probability that in the future as many products will be obtained from oil as are now produced from coal. Crude petroleum is a mixture of hydrocarbons in variable proportions with small quantities of oxygen, nitrogen, and sulphur present as impurities. Except on the oil fields, and at the pump stations, where no fuel oil is available, crude oil is very seldom used as fuel, the crude oil is always treated or refined and made into marketable products. Most crude oil as obtained from the wells are unsuitable for fuel. The object of the refiner is to subdivide the crude oil into fractions suitable for the different uses to which they are to be put.

At the present day the demands of trade call for principally:

(a) Benzines for motor fuel, cleaning and manufacturing.

(b) Kerosene (frequently called paraffin) for illuminating; also used for motor fuel.

(c) Lubricants (lubricating oil is one of the most valuable of petroleum products).

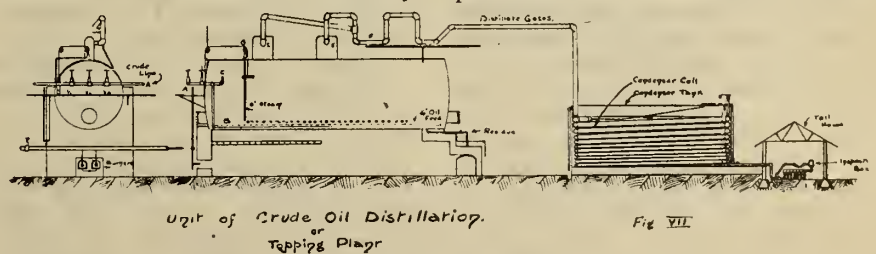
(d) Fuel oil (about 40 per cent. of all crude produced is used as fuel.)

Refineries may be roughly divided into two classes:—

First.—Refineries which treat the whole of the products obtainable from the oil by distillation, see diagram Fig. 4.

Second.—Topping plants which treat the oil with the object of obtaining only a high grade distillate (a) and (b) and a residue (c) and (d) for fuel oil, diagram Fig. 5.

In a complete refinery treating the whole of the products the crude oil is treated in a series of stills, the process is shown diagrammatically in Fig. 6, where the gasoline or benzine, kerosene, and gas oils leave the stills as a distillate, and the residue is a heavy tar or fuel oil. The benzines are further refined in steam stills. The kerosenes are also sometimes redistilled in the steam stills if a high grade produce is required, and they are treated in vertical tanks called "Agitators," where they are made "water white" by agitation with sulphuric acid and caustic soda. The residue is a heavy tar oil which can be used straight as fuel if facilities for heating to the proper temperature are available. In the Mexican Eagle Oil Refineries oil of a gravity S.G. 1.04 is used as fuel. On board ship fuel of a lighter gravity is preferred.



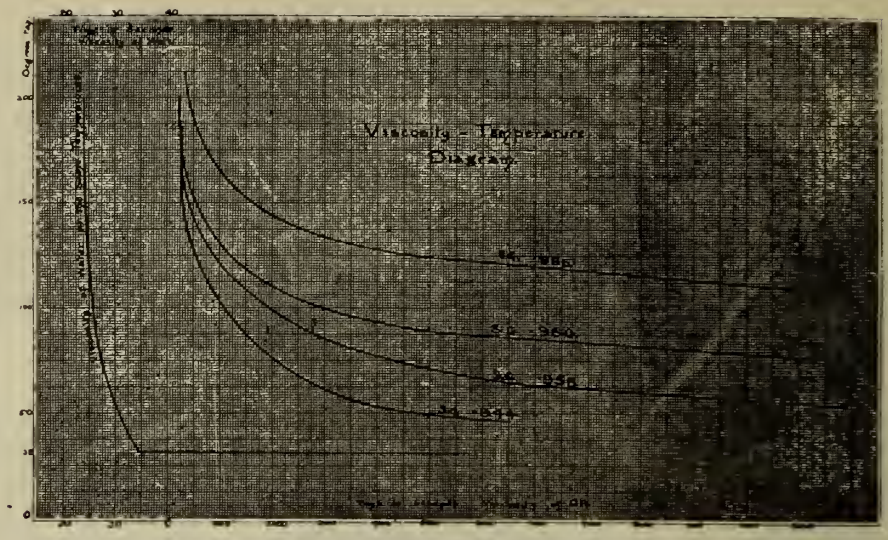
A TYPICAL UNIT.

The crude oil is pumped from the storage tank through the forewarmer to the continuous stills. The process is continuous, i.e., the crude oil enters No. 1 still, then passes on to No. 2 and so on until

*See diagram, Fig. 8.

it leaves the last still as a residue. In each still a fraction of the oil is distilled off, passes over as gas into the condenser coils where it is cooled by the surrounding water and leaves the coil as a liquid, this liquid passes into what is known as a "Tail House"; here are a number of inspection boxes (one for each still), with glass sides where the quality of the distillate coming over is observed and its gravity tested frequently. The tail house is a kind of "Junction," where the distillates are directed to their respective tanks according to their quality.

In the diagram Fig. 6 stills 1 to 4 are shown as distilling off petroleum spirit, 5 to 8 kerosene or illuminating oil, 9 to 11 gas oils, 12 to 15 heavy gas oils or heavy paraffins. If No. 4 be heavily fired it might easily happen that the distillate would have to be directed to the kerosene tank, also if 4 and 5 be lightly fired then the liquid at No. 5 "look box" would be diverted to the spirit tank instead of the kerosene tank. The crude oil left the storage tank at atmospheric temperature, and the residue finally leaves the last still at a temperature of 600 degrees Fah. The continuous stills are in appearance much like Lancashire boilers, some being "through" fired and others externally fired, they are all fired by oil fuel of the heaviest gravity. The fractions we have now obtained are still further refined. The crude spirit is gently heated in a steam still (which is a cylindrical tank with a steam coil) and the distillates are known as "aviation spirit," "motor spirits" of several qualities, and cleaning spirit, the residue, if there is any, will be kerosene. The kerosenes are treated in agitators with sulphuric acid and caustic soda, where all trace of the tar is removed and they are then ready for market. The gas oil requires no special treatment, it is used to enrich town gas, is mixed with heavy residues to make fuel oils, and is used as fuel in Diesel engines. The heavy paraffins, so called because they are heavily charged with paraffin wax, are an important fraction, because when the wax has been removed lubricating oils are obtained. The extraction of wax is an expensive process, but when ready for market it is a valuable product. The paraffin oil is chilled to a temperature of 30 degrees to 32 degrees Fah. when the wax crystallizes, and on being pumped through a filter press the wax crystals are left on the canvas filtering medium and the oil passes out free of wax, ready to be treated in the lubricating oil stills. The lubricating oil stills are oil fired, the distillate is gas oil, and the residue lubricants. The wax requires some further treatment before it is ready for market, the crude wax is rather soft and of a yellow color, but the finished product is hard and white. Lubricants also require further treatment, marine engine oil for instance requires an admixture of vegetable oil, because pure mineral oil will not saponify. You cannot obtain a lather from pure mineral oil



VISCOSITY TEMPERATURE DIAGRAM.

and water. If you have an oil that will not lather freely with a slight admixture of water, leakage from glands of reciprocating engines will wash away the oil from the bearings. In the case of turbine engines the lubricant must not be allowed to emulsify, therefore only pure mineral oil must be used for turbines.

So far we have followed the distillate through the refinery, but the tar oil which left the continuous stills as a residue is capable of further treatment. That portion of the tar oil which is not made into fuel oil is pumped to the asphalt stills, where the distillate is a heavy paraffin which is treated for extraction of wax and lubricants, and the residue is asphalt, the latter being largely used for road making and cable construction In these stills the tar enters at 450 degrees and the asphalt leaves at 750 degrees to 800 degrees Fah. according to the grade of asphalt made.

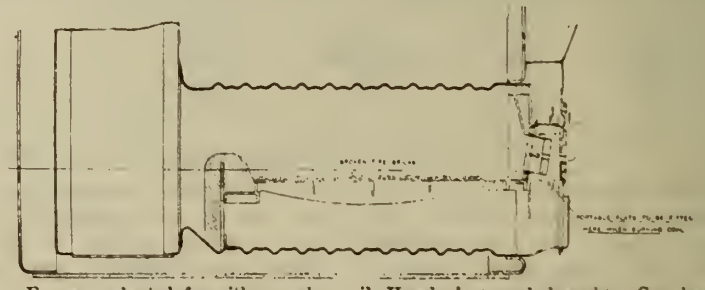
A topping plant is the simplest form of refining, it is sometimes adopted where there is a big demand for fuel oil. The light fractions are extracted by distillation and then transported to a refinery, where they can be treated and made into marketable products. The residue, as it contains all the gas oil, makes an excellent fuel of low viscosity and high calorific value. Fig. 5 represents a topping plant.

Ships.—From the refinery the oil is shipped by pipe line, tank wagons, and tank steamers to consumers in all parts of the world.

Pipe lines we have already discussed, tank wagons need no description, and tank steamers are well known to all marine engineers; they are steel boxes divided into compartments, with an engine and funnel at the after end. This appears still to be the view of many people. They are the pariahs of the shipping world when in port, and the most comfortable ships at sea.

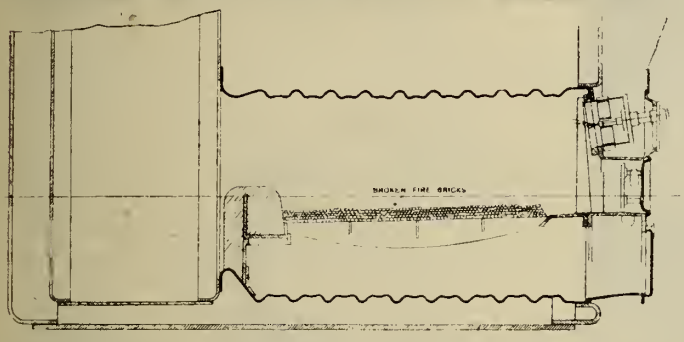
The tanker is to-day one of the most efficient ships afloat. She requires no stevedores for loading or discharging, and is capable of discharging a full cargo in less than 24 hours, the time depending upon the class of oil. The San Fernando of the Eagle Oil Transport Company is 18,000 tons d.w. capacity, and the cargo can be discharged in 18 hours under favorable conditions. The accommodation for officers and crew is luxurious compared with only a few years ago. There is accommodation for 12 passengers. Every ship in the fleet is fitted with refrigerating plant for fresh provisions, so that "salt horse" and "Harriet Lane" are almost unknown to the modern tanker. The only drawback from the officers' point of view is the short stay in port, one vessel recently made a return voyage to the Gulf of Mexico in 40 days, 10,000 miles steaming with 48 hours loading (from time of entering to leaving port).

We have now brought the oil to the

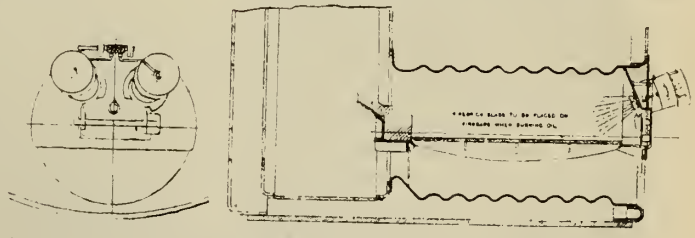


Furnace adapted for either coal or oil, Howden's forced draught. Can be changed over by merely moving broken brick and air directors or vice versa.

consumer and endeavored to show something of the nature of the stuff; it may be in order to add a few remarks regarding the handling of fuel aboard ship. It has already been remarked that 40 per cent. of all oil produced is used as fuel, and the possibilities of increased oil production in Mexico are very great, at the same time the demand for oil is increasing enormously. The superiority of liquid fuel over coal is now unchallenged and the question of its adoption is simply a matter of supply and the price at which it can be purchased. It has been said that oil won the war, and it may well be true, for the Allies controlled about 90 per cent. of the world's total production. Oil is a natural fuel for ships compared with coal, and it is now cheaper, easier to handle, and more efficient to use. Three oil fired ships will yield the same efficiency as four ships of the same tonnage burning coal. Oil with a flash point above 150 degrees Fah. is safer than coal, oil is not liable to spontaneous ignition, but if heated beyond its flash point it gives off gas that will ignite. The danger from fire is small and not greater than in the case of coal. In nearly every case of a fire in the stokehold of ships burning oil that has come to the notice of the author the cause was the leakage of hot oil from the burner or pipe at the furnace front, the usual cause is from an unlighted burner where the valve is left open and the oil runs unseen from the furnace into the bilge, and later when the burner is lighted the fire occurs. The real cause is pure carelessness.



Boiler with Howden's Forced Draught, furnace front being made to burn oil with firebars in place. Can burn coal or oil, or both together. Change from coal to oil made by covering bars with broken brick.



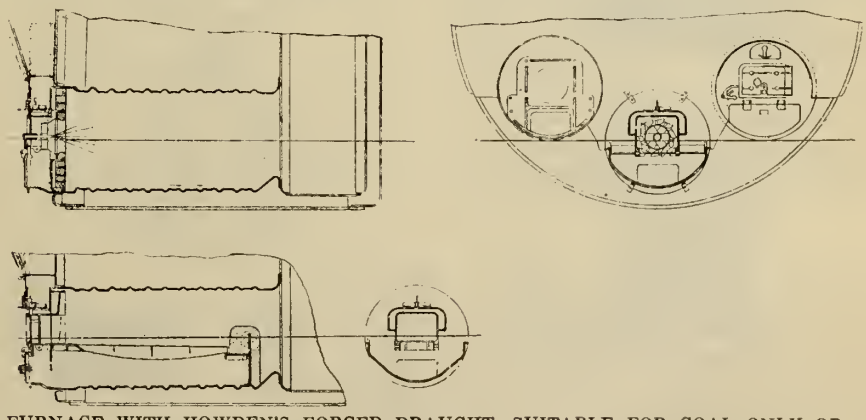
Arrangement with natural draught to burn coal or oil or both. When using oil only bars are covered with slabs.

Fuel Oil Installation. — Successful burning depends as much on the condition in which the oil is delivered to the burner as upon the type of burner. There are many fuel oil burning "systems" on the market, all more or less good. It is an axiom that the most simple installation is the most efficient, other things being equal. The first part of the installation is the bunker. The ordinary double bottom tank will carry oil satisfactorily, but they are not recommended in the case of new vessels where it is possible to have specially constructed bunker tanks owing to the danger of contamination of the fuel with water. The presence of the latter is a distinct disadvantage; besides lowering the heating value it may, in the case of heavy fuels, cause priming in the supply tank, and steam pockets in the heaters and fuel pipes to the burners. Where fuel oil is carried in double bottoms, settling tanks are necessary, where the water can be drained off. Two tanks are necessary, one being in use for separating the water, and the other acting as supply tank for the fuel pump. A steam coil is required in each tank, even if the oil is free from water, to maintain the temperature at about 80 degrees to 90 degrees Fah. to make the flow of oil to the pump easy. Strainers should always be fitted on the suction side of the pump. The fuel pump takes the oil from the supply tank through the suction strainer and delivers it through one or more heaters to the burners. The fuel pump should operate at a low piston speed, have a long stroke, and all clearances and spaces where gas pockets can form should be reduced to a minimum, the suction lift should be as low as possible. The steam driven reciprocating pump has so far held the field, but a rotary pump that would stand high pressure and give a steady delivery pressure would be ideal; there are, however, plenty of drawbacks to all the rotary pumps at present on the market. In burning fuel oils the viscosity of the oil plays an important part because success depends on the pulverization of the oil into sufficiently fine particles to ensure efficient mixing with the air admitted to the furnace, and naturally the more viscous the oil the greater the resistance to disruption. Viscosity is molecular friction, i.e., resistance to change of form, and is an expression of the time taken by a given quantity of oil to flow through a standard orifice, it is expressed in seconds. Viscosity decreases rapidly at first with rise of temperature and then more slowly as shown in diagram Fig. 8.

The mechanical atomiser is without doubt the most suitable for ships' use, and in all oil burning installations on the pressure system the fuel heater is in the author's opinion not even second to the burner. Its function is to raise the temperature of the oil to as near the firing point as convenient and to reduce the viscosity so that when forced through the sprayer the oil will enter the furnace in the form of a very fine spray or mist. There are several types of heaters in use, the most common being the condenser type and the coiled tube type, the latter is simpler and more efficient as indicated in diagram Fig. 9, which is abstracted from a paper by M. Boilla, Italian Corps of Naval Architects, which was published in "Engineering," Vol. 103, No. 2,670; this paper covered tests of oil coolers, but of course will hold good for oil heaters.

Fig. 9 is specially interesting as it shows that the spiral coil cooler 4 (or heater) is about twice as efficient as the condenser type 5, considered as a heat transmitter, besides being very much simpler in construction.

One cannot emphasize too much the importance of bringing the oil to the furnace in such a state that combustion will be rapid. In the case of oil burning the rate of combustion must be rapid because the fuel is in motion and as soon as the oil spray enters the furnace it is carried forward at the same velocity as the air of combustion. The velocity with ⅝-in. water pressure at the furnace will



FURNACE WITH HOWDEN'S FORCED DRAUGHT, SUITABLE FOR COAL ONLY OR OIL ONLY.

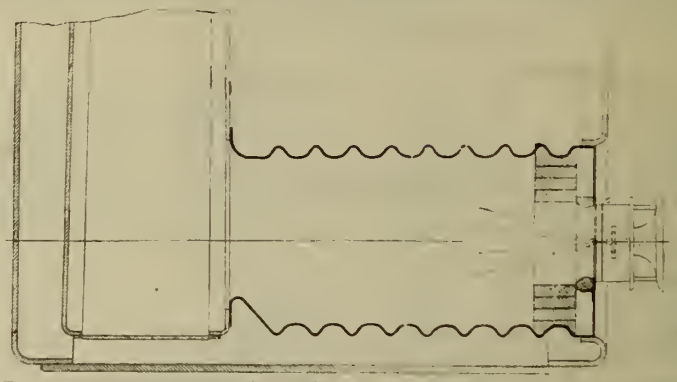
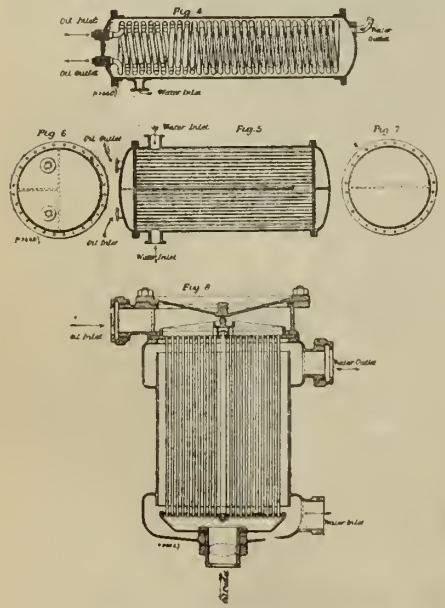
be 22 ft. per second, and with a length of furnace only 7 ft. it means that every particle of oil sprayed into the furnace must combine with the oxygen of the air, and be converted into CO_2 in the space of one-third of a second, if combustion is not completed in one-third second some of the unburnt oil comes in contact with the relatively cold furnace plate or tubes, and adhering thereto forms a tarry mass which becomes converted into carbon by the heat of the furnace. In effect the furnace is turned into a still, the fluid portion of the oil only is burned and the solid carbon remains in the furnace. The same trouble will sometimes occur due to a dirty burner nozzle, when some of the oil is allowed to impinge on the furnace tube, combustion is checked and carbon forms. As soon as the formation of carbon is noticed it should be removed to prevent the danger of local overheating, this point cannot be too strongly insisted upon. The temperature to which oil should be heated depends entirely upon the kind of oil used, each oil must be treated on its own merits. As a general rule the oil should be heated to a few degrees below its flash point, if heated above its flash point gas will form in the pipes and result in irregular intermittent flame at the burners.

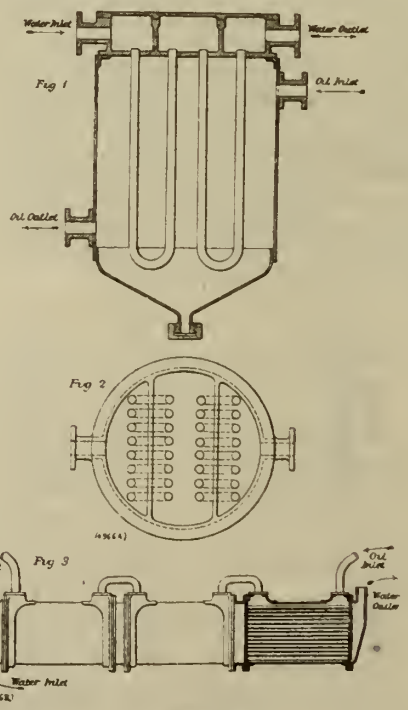
Fig. 10 shows five different furnace arrangements of oil burning. The arrangements shown on illustrations A B and C are advised by the makers when the change from coal to oil fuel and vice versa has to be frequently carried out and time does not permit of removing the firebars and backbridges as with these arrangements the time of conversion from oil to coal and vice versa is a matter of minutes only. The arrangements indicated on illustrations D and E are to be preferred where time will permit of the removal of the coal burning gear as indicated. Forced draught is preferable to natural draught. (Drawings for Fig. 10 were kindly lent me by the Wallsend Slipway & Engineering Co., Ltd.). As the fuel is in motion and not stationary as in the case of coal burning, grate area is not a factor, and furnace volume takes its place. It is furnace volume with correct admixture of air that determines the amount of fuel that a boiler can consume. One of the advantages of burning oil is the simplicity of control of the air necessary for combustion. On the other hand this may prove a disadvantage in careless hands, because it is much easier to lower the efficiency of the furnace, by admitting an excess of air, than is possible with coal. Oil usually requires about 250 cubic ft. of air per lb. of oil. The air for combustion should be raised to a temperature of not less than 300 degrees Fah. before entering the furnace; it is obviously wrong to raise the temperature of the oil to 200 degrees or 220 degrees and then admit air at 120 degrees.



Furnace arrangement for oil burning only, natural draught. To burn oil. fire bars, etc., must be stripped.



OIL HEATERS.



OIL HEATERS.

GIFT TO C. A. S. E. LIBRARY

Mr. B. G. Newton,
Manager,
Power House,
143-153 University Ave,
Toronto.

Dear Mr. Newton:—

I have been requested by Mr. A. Heath, Sec. Hamilton No. 2 C. A. S. E., to thank you most heartily for your generous contribution to our library, and can assure you that the volumes will be read with deep interest.

Bro. Heath would have written you himself, but owing to him being taken with a sudden illness he was unable to do so.

Wishing you and your paper every success.

Yours sincerely,
L. J. ELLIS,
Secretary.

The above letter was in acknowledgment of a number of books from the technical book department of the Maclean Publishing Co., presented to the C. A. S. E. through Mr. Newton, manager of Power House.

A Bulge in the Steam Drum of Water Tube Boiler

SEVERAL months ago a boiler failure occurred in the power plant of a large automobile factory, and as it was of unusual character, a brief description of it will be of interest. The boiler referred to is of the water-tube type, and has 252 tubes each 4 inches in diameter and 18 feet long, and two drums, each 48 inches in diameter and 20 feet long. The heads of the drums are 19/32 of an inch in thickness, and the shell plates are 15/32 of an inch thick. The longitudinal seams of the drums are quadruple-riveted, with double-butt straps, and have a calculated efficiency of 93.1 per cent. The boiler is operated at a pressure of 200 pounds per square inch.

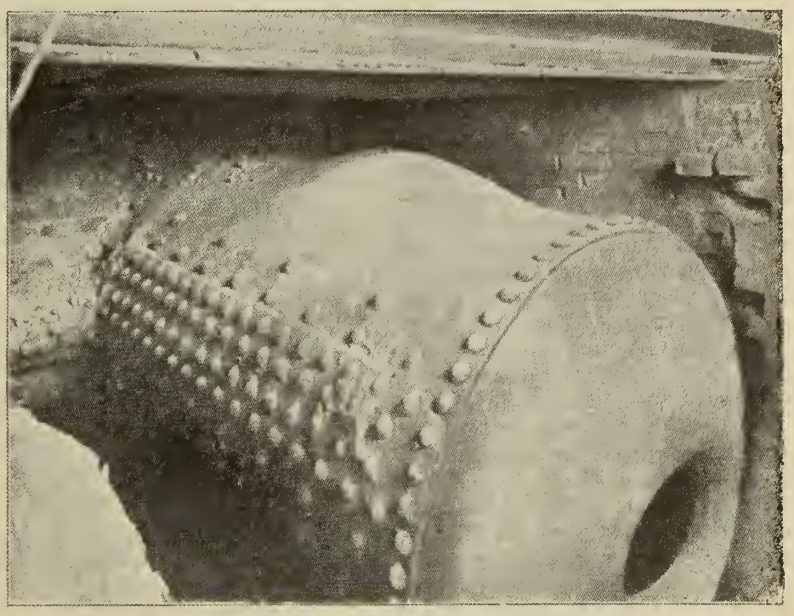
Previous to the failure the boiler had been cut out of service in order to make some maintenance repairs, and after these had been completed the boiler was filled with water for the purpose of applying a hydrostatic-pressure test. It was impossible to raise the desired pressure within the boiler, however, and the discovery was made that water was running down on the brick-work and between the tubes. Some of the brick-work at the rear of the boiler was removed and it was found that a bulge 42 inches long, 36 inches wide, and 6½ inches deep had developed in the upper shell plate of one of the drums, directly beneath the smoke breeching, and that there was an opening about three inches long in the plate at the centre of the bulge. This bulge is clearly shown in Fig. 1; and its location on the drum, and the general arrangement of the drum and breeching are shown in the line drawing Fig. 2.

The apparent explanation of this failure is that the shell of the drum became locally overheated; that the bulge was formed by the action of the internal steam pressure on the overheated part; and that finally a small opening developed at the centre of the bulge, due to the reduction in the thickness of the metal at that point.

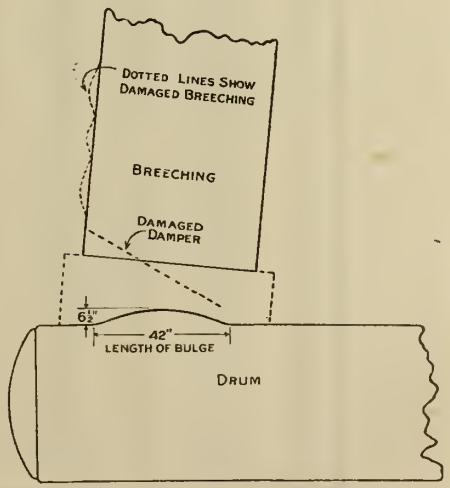
If we assume that the drum shell failed because of overheating of the metal we must assign a cause for such action. Bags and bulges in boilers are usually caused by accumulations of oil, grease, or scale, which have been deposited on the interior parts of boilers directly exposed to the flame and the products of combustion, and which form a non-conducting coating between the heat on one side of the metal plate and the water on the other side. For obvious reasons it is unlikely that deposits of this nature could have caused the trouble in the present case.

It seems probable that combustible material of some kind accumulated on the outside of the upper part of the drum where the bulge developed and, becoming ignited, caused the metal to soften and stretch under the action of the internal steam pressure. The kinds of combustible material that might have caused the damage in this particular location are practically limited to two—soot (in which may be included flue dust and cinders) and shavings. It seems rather unlikely that a dangerous temperature could have been brought about by the combustion of soot alone, under the prevailing conditions, although it is well known that this material, when deposited in combustion chambers and elsewhere about boiler settings, will remain at a high temperature for several days after the fires in the furnaces have been extinguished; and in many cases men have been seriously burned by putting their feet or hands into these hot deposits when cleaning or inspecting boilers.

There is the further possibility, however, that shavings, which were used in part as fuel for the boiler furnace, were carried along by the draft through the gas passages to the stack at which point the velocity of the current of hot air and gases became reduced so as to be no longer strong enough to sustain the shavings, which then dropped on to the top of the drum. These shavings may have become ignited, and if a considerable quantity had accumulated previous to the ignition, the resulting heat may have caused the damage.



VIEW OF BULGE IN TOP OF DRUM.



SHEWING LENGTH OF BULGE.

Fortunately, no personal injuries resulted from the accident, and the property loss was limited to the expense involved in repairing the damaged shell plate of the drum. On account of the large size of the bulge and the high pressure carried on the boiler, it was recommended that a new course be substituted for the damaged one, rather than to attempt to force the bulge back into position and apply a patch. It was also recommended that doors be placed in the brick work between the breeching and the drums on the boiler, to give access for cleaning out accumulations of soot, as often as might be found necessary.—Traveller's Standard.

Power for London.—The Ontario Power Commission has approved of plans for cost $35,000, to accommodate the new industrial area that the city has established there. Work will begin at the first of the new year and filtration equipment will also be installed at the Horton street pumping station at a cost of $55,000.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE HAVE dealt in the last article with the latent heat of steam, and have of course assumed that we were dealing with saturated steam. It would be as well at this juncture to define the different kinds of steam with which we have to deal in engineering practice. We will first define saturated or dry steam.

Saturated Steam

Saturated or dry steam is steam which is in contact with the liquid from which it has been evaporated, and is at the same temperature as that liquid. It holds no moisture in suppension, but being at the same temperature as the liquid, will liquefy under a small reduction of temperature. It is also called saturated steam because it is at its maximum density for the corresponding temperature.

Wet Steam

Wet steam is steam that holds in suspension a certain amount of moisture. The effect of this is to lower the total heat of a given quantity of the mixture of steam and water in proportion to the dryness fraction. For instance, if the mixture was 90 per cent. steam and 10 per cent. water, the total heat would be less by the following amount. If the total heat of dry steam at atmospheric pressure is 1146, this being made up of S plus H, then the total heat of steam with 10 per cent. moisture would be only S plus .9H. The dryness fraction would be .9 or 9/10. The total heat would then be 180 plus .9x966, which would be 1049.4, instead of 1146 with dry steam.

Superheated steam is steam which is not in contact with the water from which it has been evaporated, and is at a higher temperature than that corresponding to its pressure. If, for instance, we had atmospheric pressure steam, saturated, its temperature would be 212 degrees. If we had steam at the same pressure, but at 250 degrees temperature, we should have 38 degrees superheat in the steam.

The Use of the Steam Tables

The properties of saturated steam at different temperatures and pressures have been made up in the form of tables, which are exceedingly useful to the engineer, who has not the time to spare to work out intricate formulae whenever he has a problem to deal with. These tables are easy to use when the principles are understood. The following table shows the properties of steam from 1 pound absolute to 400 pounds absolute pressure. They are taken from Kempe's Hand Book, and are not exact, but sufficiently close for the purpose of explanation. The first column gives the pressure in pounds per square inch above a vacuum, or absolute pressure. The gauge pressure can be found by subtracting 14.7 from the pressure given. The second column gives the temperature of the steam in degrees Fahrenheit, which saturated steam should be at the corresponding pressure. If below that temperature, the steam is wet, while if above it the steam is superheated. The third column gives the total heat in steam above 32 degrees, and includes sensible heat, or is equal to (t—32) plus H. The heat in the liquid above 32 degrees is shown in the next column, and the latent heat in the fifth column. The sum of the fourth and fifth column is equal to the third column, or the fourth column is equal to S and the fifth column to H, while the third is the sum of S plus H. Remember that sensible heat is always reckoned from 32 degrees as a starting point. The sixth column gives the density of the steam, or the weight of a cubic foot in pounds, at the given temperature and pressure. The lower the pressure the less the density, or in other words, the greater volume occupied by one pound of the gas. The volume of steam at atmospheric pressure is about 1600 times that of the water from which it is evaporated, but one pound of water will make exactly one pound of steam. As the pressure increases the volume decreases, and density increases. The total heat increases, but the latent heat decreases, and the sensible heat increases. This table also gives the factor of evaporation. This factor of evaporation is something that should be understood by the engineer, especially if he is ever going to make tests.

The quantity of heat units required to evaporate one pound of water into one pound of steam at atmospheric pressure is 966.6. The total heat in the

steam above 32 is 1146.6 B.T.U. If we take steam at 50 lbs. per square inch the total heat will be 1172.7 B. T. U. Then the ratio of the total heat of steam at atmospheric pressure to the total heat of steam at 65 absolute pressure will be 1172.7 divided by 1146.6, which is 1.02. This figure will be the factor of evaporation, and the way it is used is this. Suppose that 10 lbs. of steam had been evaporated from water at 32 degrees into steam at 50 lbs. per square inch, or 65 lbs. absolute. We wish to find how this compares to the amount that would have been evaporated into steam at atmospheric pressure from the same temperature. The factor of evaporation is used as a multiplier, and we have 10 x 1.02=10.2 lbs. This is an example of the factor of evaporation at 212 degrees, as stated at the head of the table. However, in actual practice, we do not have water at 32 degrees, or any other definite temperature. Therefore, all evaporation performances are based on the evaporation of water from 212 degrees into steam at 212 degrees, and all boiler performances are reduced to that equivalent. Suppose now we had a boiler, which, under a test, had evaporated 10,000 pounds of water from 180 degrees into steam at 145 lbs. gauge pressure, and we wished to compare this performance with the evaporation of the same quantity of water from and at 212 degrees, in order to get the boiler horsepower. We would first find the factor of evaporation. The absolute pressure will be 160 pounds, and the temperature corresponding to this will be 363.4 degrees. The total heat is 1192.8 and the latent heat is 857.4. What we are interested in is the total heat in the steam above 32. As the feed water was at 180 to begin with, the total heat we have added will be 1192.8—148=1044.8. By taking the heat in the liquid above 32, which is 335.4, and subtracting 148 we get 187.4 and this added to the latent heat, 857.4, gives 1044.8 the same as before. That means that the total heat added per pound of water is more than would be required to evaporate it from and at 212, in the proportion of 966.6: 1044.8, which is 1.08. This will be the factor of equivalent evaporation, or as usually called, the factor of evaporation. The equivalent evaporation from and at 212 is then 10000 x 1.08, which gives 10800.

Suppose now that we had the same water evaporated from feed water at 210 into steam at 50 lbs. gauge pressure, or 65 lbs. absolute. The total heat in the steam is 1172.7 and the heat added will be 994.7. The factor of evaporation in this case would be 966.6:994.7 or 1.02, or 10200 lbs. would be the equivalent evaporation. Now suppose that we had been feeding the boilers through an economizer that raised the temperature to 260 degrees before the water entered the boiler, and that the steam was at 145 lbs. gauge pressure. The total heat would be 1192.8, and the total heat added would be 1192.8—288= 964.8. The factor of evaporation would now be 966.6:964.8=.998. That means that the amount of water that would have been evaporated from and at 212 would have been only 9980 lbs. The thing to remember is that the latent heat at 212, or a better way to put it, the heat of vaporization at atmospheric pressure, must be divided into the heat added at the temperature and latent heat of the steam which is to be compared, less the number of degrees above 32 that the feed water is at. To put it into an easy formula let H equal the total heat of the steam above 32, and the temperature of the feed water.

$$\frac{H-(t-32)}{966.6}=\text{Factor of evaporation}$$

$$\frac{1192.8-(260-32)}{966.6}=\frac{1192.8-228}{966.6}$$

$$\frac{964.8}{966.6}=.998$$

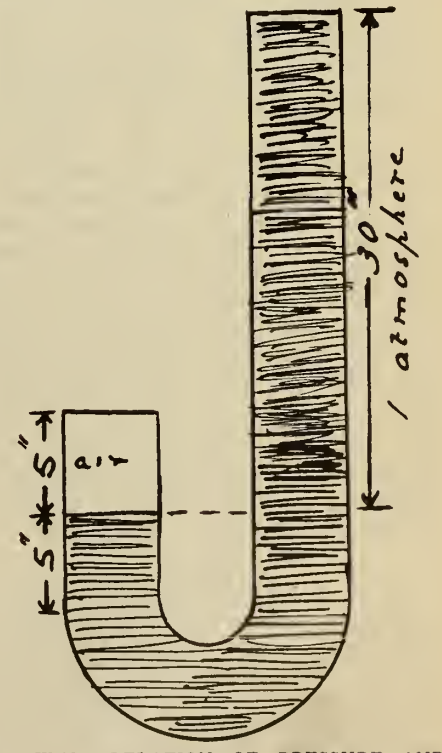
Having now got an understanding of what steam is, and the amount of energy it contains in the form of heat units, we are in a better position to study its use in the forms we are acquainted with. In order to do this we shall have to go back a little bit, and make acquaintance with some ancient laws on the behavior of gases.

Steam follows very closely the law of gases as propounded by Boyle, although not altogether so. This law is that pressure varies inversely as the volume, and the product of the pressure and volume of a gas that is expanding will always be constant. We will examine this a bit more thoroughly so that it becomes clear to the student.

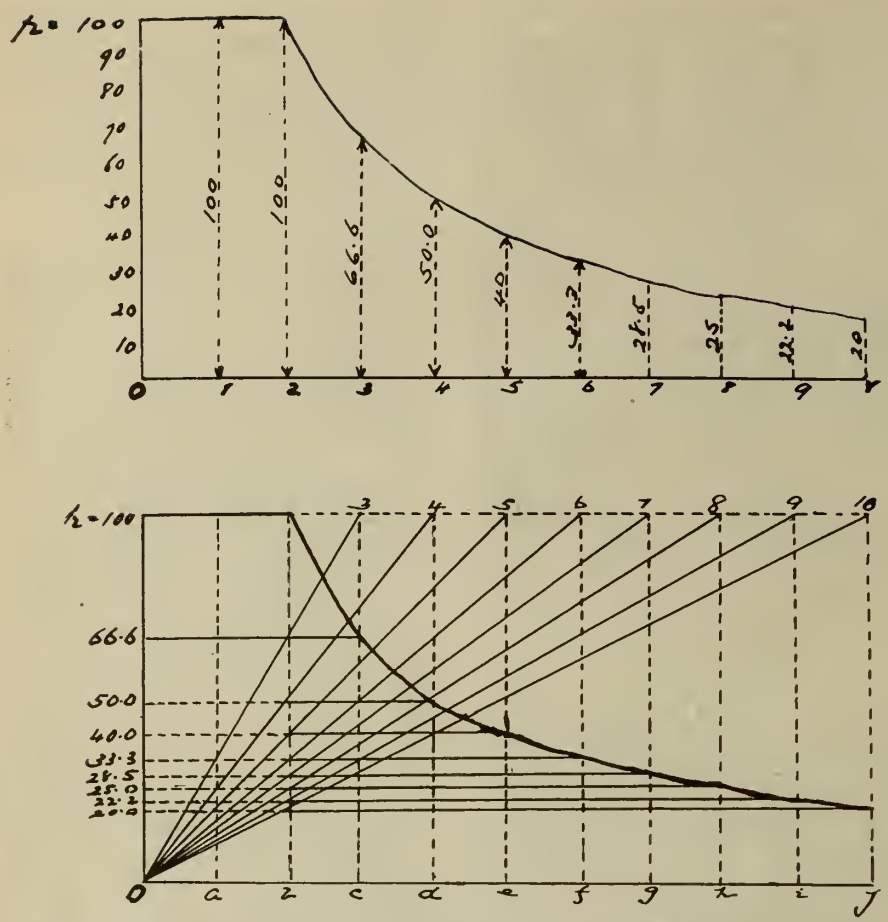
If we take a bent tube, the short leg of which is 10 inches long and the long leg 35 inches long, and close the top of the short leg with a plug, leaving the top of the long leg open, we shall have a pressure in the tube due to the atmosphere, or say 15 lbs. approximately. If now we take a quantity of mercury, and fill the long leg until the mercury stands just 30 inches above that in the short leg, we shall have exactly 5 inches of mercury in the short leg. But as we have a column of mercury 30 inches above the level of the mercury in the short tube, we have the equivalent of 15 lbs. pressure in addition to the pressure due to the atmosphere that was already there. Further, the air contained in the short leg of the tube has been compressed into just half its former volume. Therefore, if the first pressure in the tube was 1, and the volume 1, we now have a pressure of 2 and a volume of ½, which gives the same result when multiplied together as the first pressure and volume. This is a simple proof of Boyle's law, and one easily understood. By means of a diagram, in which the horizontal lines are measures of volume, and the vertical lines measures of pressure, the law can be very clearly shown. We shall show first the method of constructing the diagram from the calculation of the different pressures and volumes and secondly the method of constructing the diagram without any calculation.

Boyle's law is usually expressed mathematically as follows: $pv = c$. It follows then that $p = \frac{c}{v}$ and from this we can construct a curve which will show the pressure of an expanding gas at any point in the volume of its expansion.

In the following diagram let the vertical line represent pressures to a scale, and the horizontal line volumes to any convenient scale. The starting point 0 of the two lines will be the zero of pressure and volume. Divide the vertical line into 10 equal parts, and the horizontal line into the same number. Let us assume that the steam is at an absolute pressure of 100 lbs., and that after filling two spaces in the horizontal direction, it is cut off and allowed to expand. The product of pressure and volume at the point of cut off will then be 100 x 2=200. At the next division the pressure will be found by the expression $p = \frac{c}{v}$ or $p = \frac{200}{3} = 66.6$. At the 4th division it will be 50, at the 5th 40, at the 6th 33.3, at the 7th 28.5, at the 8th 25, at the 9th 22.22 and at the tenth 20. The average pressure over the whole expansion will be the sum of these different pressures divided by 10 or 68.56.



SHOWING RELATION OF PRESSURE AND VOLUME ACCORDING TO BOYLE'S LAW.



CURVES OF EXPANDING STEAM. TOP DIAGRAM IS CONSTRUCTED BY CALCULATION, AND LOWER ONE BY GRAPHIC CONSTRUCTION.

To obtain the same result graphically, first lay out the two lines representing pressure and volume. Make the divisions as before, drawing the vertical lines at each division. From the point O draw lines joining the division lines at the same height as the pressure line, or at the top of the diagram. From the point on the vertical line where the diagonal lines cut it, draw horizontal lines to each succeeding division line, as shown in the diagram. Then the height on each division line where the horizontal lines cut them, will represent pressure at that point, further, the area of each parallellogram will be equal, thus proving again the law that $pv=c$.

The actual behaviour of steam expanding in an engine is not quite in accordance with these laws, as we have said before, but we cannot enter into this question at this stage of the study of steam. The behaviour of steam expanding in an engine will be taken up in future lessons, starting first with the application of these diagrams to the performance of steam in the cylinder.

The R. S. Leitch Co. have taken over the agency in Ontario of the Armstrong steam trap, made by the Armstrong Machine Works, Three Rivers, Michigan. The trap is made on the inverted submerged bucket system, a different system than any other trap on the market, it being a patented article.

Catalogues

We have received a copy of MacRae's Blue Book, which is a very comprehensive directory of manufacturers and manufactured articles. The first 300 pages are devoted to a catalogue section, which contains in condensed form the catalogues of a large number of manufacturers of various lines. This is followed by an alphabetical address section, in which over 30,000 names of manufacturers are found, while the next section is a classified material section, which covers practically every material used in industry. Other sections are a trade name index, a section devoted to data of a very varied kind, such as would be useful to the specifying engineer or the purchasing agent. Standard list prices of building material and iron and steel products form another department, and a net discount computer is included. This is certainly a very valuable volume to be on the shelf of every purchasing agent and consulting engineer. It is well and strongly bound, as a volume intended for hard use should be, and is crammed full of useful information.

H. L. Peiler, manager of the Mason Regulator Company, has just returned from a very successful business trip in the Eastern Provinces.

TAPPING SOFT METALS

In tapping soft metals such as aluminum, there is quite often some difficulty in starting the thread, as the tap will at first either ream out the hole in a partial manner or strip the thread after it is started.

Both these dangers can be avoided, and perhaps the simplest method of all is to make an accurately threaded guide block about the same depth as an ordinary nut.

By placing this guide block in correct position over the hole to be tapped, no trouble will be experienced as the tap must then travel through the soft metal at a predetermined rate. Of course the guide block must be clamped to the work. It is essential that the block be fastened, and another point to be watched is the use of a good lubricant.

Whenever dealing with soft metals, do not rush the job. Humor it, for owing to the weakness of the metal it is likely to break away if too much force is used. Even copper can be stripped if two much force is adopted. If cutting threads on the lathe the danger is not so great but even there it is necessary to use the best of care. Above all see that the cutting tools are sharp. If you don't the results will be far from perfect.

Some recent tests to determine the proper amount of air required for special thermit welding gasoline and compressed air preheaters showed that 25 pounds per square inch seems to be a practical minimum. At this pressure, a single burner preheater will require approximately 25 cubic feet of free air per minute and a double burner preheater approximately 50 cubic feet. For very large welds, where the walls of the molds are thick and the preheater gates longer than usual, a pressure of 40 pounds per square inch would be advisable. This would require approximately 35 cubic feet of free air per minute for a single burner and 70 cubic feet of free per minute for a double burner.

GOOD WORK OF RECIPROCATOR

The splendid performance of the S.S. Kandahar owned by Ellerman & Bucknell has recently attracted considerable attention.

This vessel is of 10,750 D.W. tonnage, equipped with triple expansion, engines, H.P. 25½ inches, M.P. 43½ iches, L.P. 76 inches, stroke 51 inches, developing 3,200 I.H.P. at a speed of 12 knots. It is fitted with three single end Scotch boilers with Howden forced draft, and with fire tube superheaters delivering 200 deg. at the main engine throttle. It burns about 42½ tons of coal per 24 hours or about 1.24 pounds of coal per I.H.P. for all purposes.

This vessel has been operating since 1913.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

DUPLEX PUMP

Question.—What is the cause of piston on duplex pump having a longer stroke one side than the other? Also state cause of pounding in pipes running to tank when pumping?

Answer:—

The uneven stroke on the duplex pump is usually the result of defective valves or piston packing on the side which takes the longer stroke. The steam valves being worked from opposite sides of the pump, the lever on the side taking the long stroke moves the steam valve on the other side before that piston has completed its stroke. It may also be caused by too much lost motion on the spindle of the valve on the side taking the short stroke. The reason of the pounding in the pipes may also be the uneven strokes causing the water to be delivered in jerks instead of regularly. An air vessel on the discharge pipe would cure this trouble.

* * *

MARINE ENGINE

Question.—We are setting up a marine engine to do stationary work, one that has been used in a steamer. She is 15 x 30 x 22, has a condenser, a circulating pump and a pump on the engine to pump the condensed water to the hot well. We would like to do away with the condenser, that would do away with the hot well pump of the engine and the circulating pump, as we have a limited floor space.

We have a good feed water supply and if we used the exhaust steam from this engine in feed water heaters would we get as much power as we would have obtained had we used the condenser?

If it would not be too much bother would like you to drop me a line as soon as possible in answer to this question.

Answer.—I note that you are intending to set up a marine engine for stationary work, and that you suggest doing away with the condenser. You cannot hope to obtain anything like as much power without the condenser as with it, and furthermore your coal consumption will be much higher. I would advise you unless you want the exhaust steam for heating purposes to install a condenser. You did not say whether it is a jet or surface condenser. For stationary purposes where you do not require the condensate for feed water purposes you could install a jet condenser which would take up less space than a surface condenser with its air and circulation pump. To run an engine with atmospheric exhaust will cost you from 15 to 20 per cent. more in fuel for the same power, or give you 15 to 20 per cent. less power with the same fuel. The feed water heater would occupy almost as much floor space as the jet condenser, and the most you can save from heating feed water would be 1% for every 11 degrees the water is heated. If you raised the feed from 60 to 200, or 140 degrees, the saving would be only about 12%. With a 25 inch vacuum you would have the feed water in the hot well at 125 degrees, so you would only be losing about 7% of the heating, against a gain of 20% by condensing, giving you a net gain of 13% by condensing.

* * *

GAUGE GLASSES

Question.—Is there a law about having guards on gauge glasses?

Answer.—There is no law as far as we are aware compelling glasses to be protected; however it is a very simple matter for any engineer who desires protection, to fit these guards on the gauge mounting. A half round sheet of tin with a slot the length of the glass so that the water can be seen, is a good and simple arrangement, or else wire glass guards can be purchased from almost any engineering supply house.

* * *

OVERHEATED PLATE

Question:—How can I tell whether a boiler plate has been overheated? I heard some engineers talking about boilers being overheated. I want to know what they mean. I look after a heating boiler 2 pounds per square inch?

Answer:—If from any cause, such as scale, oil, or grease getting on the water surface of the plate, its heat conductivity is impaired, then instead of the heat being conducted through the plate, it will be absorbed by it. This causes the plate to be raised in temperature, possibly to a red heat, and in this state its ductility or flexibility is so much increased that it cannot maintain its shape against the internal pressure. This will result in a bulge in the plate, and according to the depth of the bulge the metal will be drawn out or made thinner. This effect may be sufficient to cause rupture. When the plate gives, the scale will be cracked away, allowing the water to reach the plate and cool it. This may occur sufficiently early to prevent the bulge assuming large dimensions. In other cases the heating may be confined to a small area, when a deep blister will be formed, and the plate drawn down thin enough to rupture. Be careful to keep the boiler clean and then you will not have the unpleasant practical lesson of what overheating means.

* * *

TESTING FOR ACID

Question:—How can I test boiler feed for acid and for alkalinity?

Answer:—The usual method is to use litmus paper, which will turn pink if water is acid, and yellow if alkaline. A better test is to use a few drops of methyl orange, which turns yellow if the water is alkaline, or a decided pink if acid. Phenolphthalein added to the water will make it a cloudy white if acid, and magenta if alkaline.

NEW INDUSTRY AT PORT ARTHUR

In a large advertisement appearing in a recent edition of a Port Arthur paper, there is an announcement of the Port Arthur Shipbuilding Co., in which is recounted the falling off in the shipbuilding industry. The announcement goes on to state:

"Anticipating this condition of affairs, we have commenced the construction of pulp and paper machinery, and compressed air mine shovels, which work will, we hope, take up the slack caused by the falling off in shipbuilding. We have, however, in this new line, to go into competition with established manufacturers of long experience in this class of work. To succeed will mean not only continued prosperity for us, but the continuation of our quota of the prosperity of our city and the steady employment of the men who comprise our organization. Such success is what we are striving to attain for 1921, and we ask each and every one of our employees to unite with us in this purpose for the good of all concerned, and the welfare of the city in which we live. Of the citizens of Port Arthur, we ask a continuation of the co-operation and goodwill that they have given us in the past."

Not Alone Here

WHILE we know that the average boiler performance in this country and the United States is very low in point of efficiency, it is somewhat of a negative satisfaction to know that we are not alone in this defect. It is a negative satisfaction, because one does not like to hear of inefficiency in any branch of engineering, or in any country. Inefficiency in one country while it may help another country in a way, is yet a detriment, as it is when concerned with the burning of fuel a loss to the world. These remarks are occasioned by the perusal of an article in an English technical journal deprecating the low standard reached in the combustion of fuel under boilers generally, and the wide discrepancy between the best practice and the worst. There is a range of 100 per cent. in a number of tests made between the highest and the lowest. There should be no possibility in these days for any such variation in performance. It is quite possible for the average hand-fired boiler plant to reach an efficiency of 70 per cent., but there are a very very few that ever do it. The mere installation of mechanical firing equipment is not a guarantee of improved performance, because a mechanical equipment not properly looked after and maintained can be just as much lacking in efficiency as any hand-fired installation. The maintaining of a reasonable degree of good performance rests in the final analysis on the operating engineer, and it is strictly up to him to get the best results possible with the equipment he has. If every operating engineer sets his mind on getting better results this year than last, the end of 1921 will show a better average efficiency for the whole country. Remember that in a factory where heating is required for a large part of the year, and steam is required for industrial purposes, a well operated and efficiently run steam plant can hold its own against any competition that can be brought against it.

Saving the Oil

SECRETARY DANIELS, of the U.S. Navy, has been promulgating his views on the fuel question, and it is his opinion that oil fuel should be kept entirely for marine use. Coal and water power should be used exclusively on shore. Furthermore, he thinks that all the coal and all the water power should be nationalised. Judging from the results of the nationalisation of the railroads in the States during the war, one would not expect much enthusiastic agreement with this proposition.

We are of the opinion that oil fuel for boilers is not a method of conservation. There is as much room for waste and inefficiency in burning oil under boilers as in burning coal. The logical place for the burning of oil is in the internal combustion engine, where the crude oil can be burned with an expenditure of less than half a pound of oil per brake horsepower. Of course, in high speed passenger and naval vessels, there is a legitimate use for oil fuel, but in stationary work, the development should be more towards the utilization of the low grade coals and lignites, which afford a huge reserve. Work is being done along these lines, and it is to the results of these experiments that we must eventually look for a cheap fuel supply.

Editorial Briefs

With stores shouting half-price sales and New York funds dangling around 18 per cent., a person has to have a pretty fair education to reckon what his week's pay is really worth.

Doctors in Paris believe that the skin may be so developed that it may perform the function of eyes. Thus will preference be given to the man who sprouts an eye in the back of his neck when a foreman is wanted for a gang of day workers.

The way in which American settlers are coming to this country with their effects and their cash and the number of American firms already established here and coming over in 1921 is evidence that they have a lot of real dollars and cents faith in the future of this country. Were there any doubt in the matter, these shrewd people would not be staking millions of dollars in property and building here.

The death of Horace E. Dodge following, within a few months the passing of his brother John F., removes from the mechanical world two brothers who started in a small way, faced the vicissitudes of business and conquered. The father of these boys was the owner of a small machine shop, in which the lads learned their trade and undoubtedly learned it well. They made typesetting machines, then bicycles. Following this they turned to automobile parts and then to the finished article, until to-day their plant covers over 100 acres of floor space.

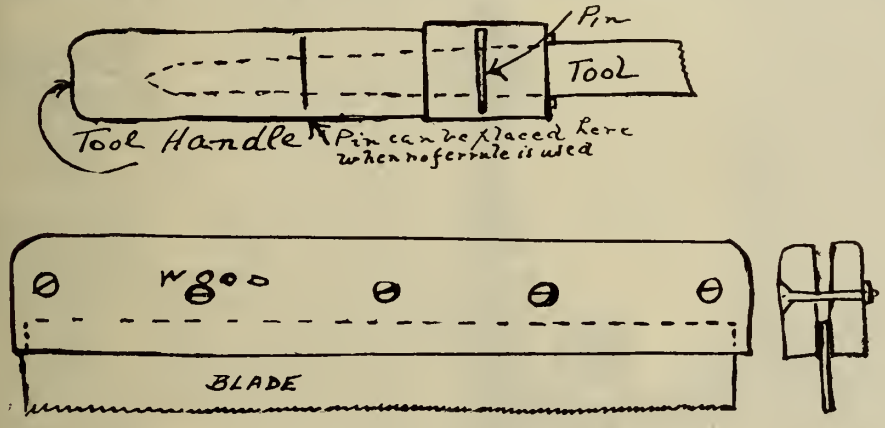
The Operators' Point of View

HANDY TOOLS

When a complicated idea occurs to a man he will take a pen and paper, sit down and work it out. When the same man is put to some inconvenience for the want of some minor article, he is apt as not to do some cussing and endeavor to do without the article missing. Perhaps if he had used his brains to think a few moments he could have solved his difficulty by using a makeshift. Many a little kink used in an emergency has saved a world of trouble and lost time. Such an article is shown in the illustration. It is so plain that little explanation is required. If you wish to make some shallow cuts in iron and have no saw frame but have saw-blades or part of a saw blade, a couple of pieces of hardwood and a few ¼-inch stove bolts will help you out. The blade is simply placed between the two pieces of wood and the bolts tightened up. You will be surprised when you try the idea out to find that a very narrow grip on the saw blade will hold it so that considerable pressure can be placed on the top and the blade will not slip.

Another little kink is also shown. It is nothing more than an iron or steel pin driven through a tool handle, tool and ferrule, holes being first made through the three articles to take the pin. Such a pin being used will allow considerable hammering on the end of the wood handle with little danger of splitting it. It also prevents the possibility of losing the ferrule should it become loose. You can take a round piece of iron, sharpen one end to form the screw driving end of a screw driver, drill a hole in the other end to take the pin. Assemble it in the handle, and you have a screw driver with the blade always in the handle.

This idea is handy to use in all tools, with wood handles, that are turned when being used. JOHN THOM.



SCREW DRIVER AND HACK SAW HOLDER

KILOWATTS AND HORSEPOWER

L. A. LaRue

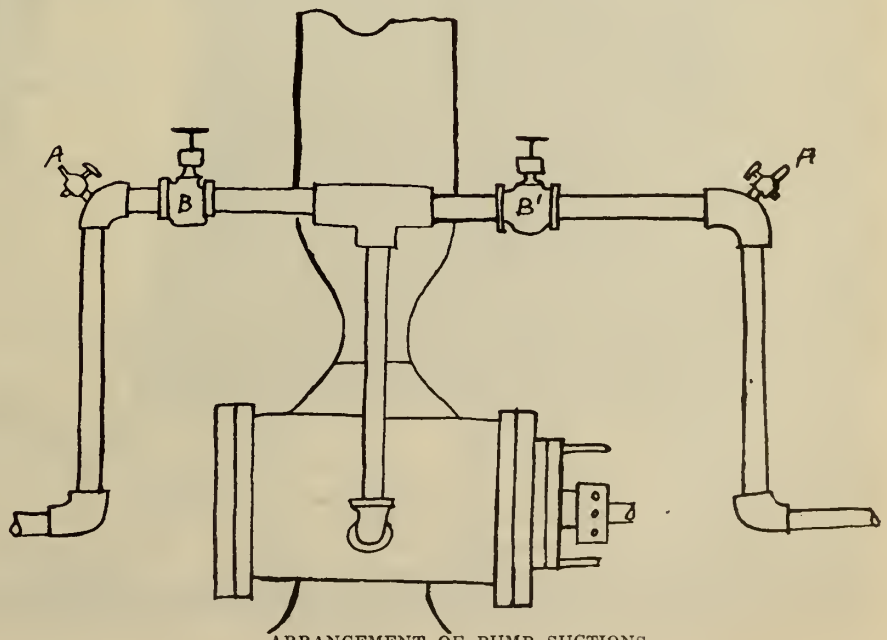
One horsepower is equal to 746 watts, hence a horsepower is equal to 0.746 kilowatts. Therefore, to reduce kilowatts to horse power, divide by 0.746, or, for an approximate result, multiply by 1 1-3. Having kilowatts, to get horsepower, multiply by 0.746, or multiply by ¾.

PREVENTING FREEZING OF SUCTION

A steam pump, in a country district, had two suction pipes connected to different sources of supply some distance from the pump. Part of these pipes ran through space not heated in the winter and it was necessary to have the particular pipe empty when water was not being drawn through it, both pipes being emptied at times. The pump itself was in a heated building and was in no danger from frost. The pump suction pipes were installed as shown. By closing either valve the water could be taken from the desired supply hole, or from both at the same time by leaving both open. When one pipe only was in use the valve on the other pipe was closed and the pet cock opened. This allowed air to enter and the pipe to empty. To prevent possibility of losing the water in the pump should the valves and air cocks be left open at the same time, the pipe was raised at the pump as shown. This made it a certainty that there would always be water in the pump. Otherwise the pump would have to be primed.

JAMES ELLETHORN.

The Canadian Tygrad Engine Co., Toronto, has awarded contract for its carburetor plant to be erected on Kingston Road at a cost of $40,000, to the Trussed Concrete Steel Co., 34 King Street West, Toronto.



ARRANGEMENT OF PUMP SUCTIONS

Lubrication and Its Importance to Industry

By A. H. NOYES

THIS is truly the age of machinery. The mechanical inventions of the past fifty years have been marvelous. Watching certain modern machines, with their giant arms, manipulating with absolute ease seemingly impossible loads, and watching still another type of modern machine performing operations delicate enough for a woman's fingers, it is almost impossible to refrain from looking for the god, sometimes the demon, who must be hiding behind the machine and working the levers.

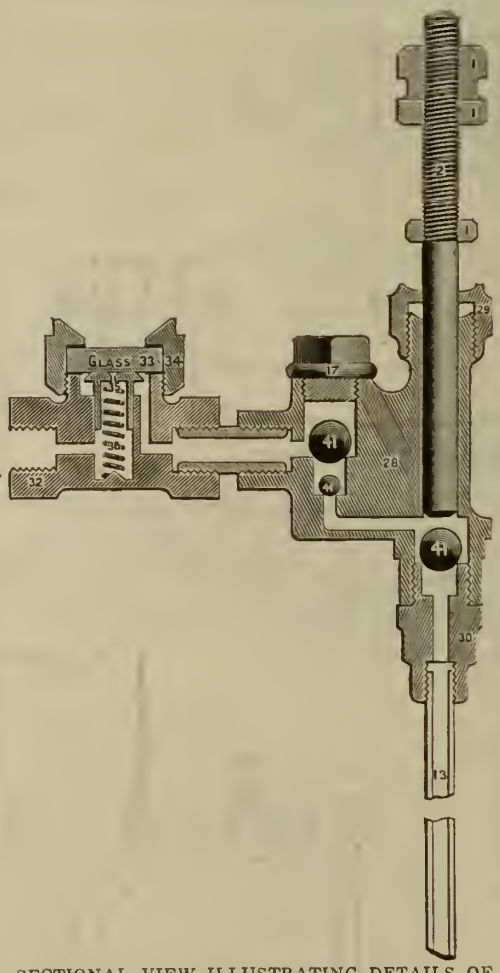
Did you ever stop to think that this intricate and often delicate machinery depends absolutely upon one thing, a thing that can not only stop every current and cog and wheel but damage the whole apparatus beyond repair? Does one person in a thousand realize that this tiny thing, which nevertheless has the life of the whole tremendous mass of machinery in its power, is a drop of oil? What irrevocable damage is caused by two metal surfaces sliding, rolling or grinding over each other, if there is no lubricating substance between.

Ever since machinery has been in existence, lubrication has been its companion. In fact, it existed even before there were machines, when it was simply a case of reducing the power necessary to push one surface over another. People did not know the word friction, did not even know what lubricant meant, but they did know that a little bit of fat or grease made the sliding a lot easier. Even today, in the island of Madeira, the natives' ox-carts have runners instead of wheels, and to assist the patient animal, the driver runs ahead with the "grease rag," with which he smears the cobble stones of the roads. From years of greasing they look like polished ebony.

It is a far call from a wooden sled sliding on cobble stones to two highly polished metal surfaces gliding over each other in a delicate machine, to the powerful piston of a great ship sliding back and forth in the cylinder pushing the whole weight of the ship before it, or the wonderful roller and ball bearings which do so much to reduce friction, and consequently the cost of motive power today. So it is a far call from the grease rag of the Madeira native to the marvelous automatic force feed lubrication of the present day's genius. If the yelling, gesturing native become a bit too tired of running back and forth with his "grease rag" it is only a little more sweat and effort from the patient ox that is at stake, no one hurt, no damage done, only a little more time wasted, and time is a drug on the market with the natives.

But when two polished metal surfaces slide over each other, unoiled, they have a fatal tendency to stick together. Then what? Bearings destroyed, cars delayed, ships at the mercy of wind and wave, time which is worth millions lost, contracts forfeited, and incalculable damage done. Lubrication, then, becomes the sine qua non of industry. This seemingly unimportant thing becomes of prime importance and must be considered from two viewpoints. The first of these is the selection of the lubricant, and the second is the continuous application of this lubricant to the bearings in the amount required.

Only a child would attempt to lubricate the highly polished bearings of an



SECTIONAL VIEW ILLUSTRATING DETAILS OF THE FEEDING MECHANISM.

astronomical instrument with graphite, or to put crude oil in the delicate movements of a watch, neither would highly refined machine oil be of great service in the bearing of a cement crusher. But between these wide limits there is an infinite number of degrees of refinement, and much of the life of a machine depends upon the selection of exactly the right lubricant.

However, the utmost care and the most expert knowledge might be exercised in selecting just the lubricant suited for a machine, and little use would it be if it never reached the bearings. A poor lubricant that reaches the spot is much better than a perfect one that stays in the oil tank. This is where the element of human frailty formerly entered. The man with the oil can was often more important than the president of the company, his mistakes would sometimes be more costly, and both the president and the oiler were liable to error. Men have such excellent "forgetteries." Add to that characteristic the universal tendency to carelessness and to "slighting the job," and you have in humanity a woefully deficient oiling machine.

Some accurate and reliable lubricating instrument had, therefore, to be devised. There were, however, certain advantages that the human oiler did have: the machine which should replace him must incorporate all of these advantages to a higher degree, and, in addition, it must not get out of order. So came into existence the force feed lubricator. For instance, the lubricator must start work as soon as the machine starts and must deliver oil in proportion to its needs. A ratchet driven pump was found to best fulfill these two conditions. The motor driven pump of course does not vary its stream of oil and the hydrostatic pump was no more successful. In the latter type the steam condenses in the condensing chamber and forces the oil drop by drop to the bearings. This is successful enough when the machine is working slowly, but when it works rapidly, so much live steam is passing into the chamber that it does not condense fast enough and therefore does not feed the required amount of oil just when the need is greatest.

Hence the ratchet driven pump, to my mind, has almost supplanted other types. It derives its power from a moving part of the machine and consequently stops and starts and accelerates or retards its own speed exactly with the machine. It therefore regulates its delivery in direct proportion to the needs of the machine.

Some of the pumps are fitted with worm gears. These are especially adapted to high speed steam units such as direct connected light engines and sawmill steam feeds of the reversible rotary type. But the "man with the oil can" was not affected by heat or cold, and if working in flying dust he might rub his inflamed eyes, but he still kept on oiling. The best modern force feed lubricators have heaters incorporated in them and they are more oblivious to cold than any man. They do not solidify in winter, therefore, and they do not over-

15 Sales Offices Backed by the 100% Standard of Quality

THE Canadian Fairbanks-Morse Company Limited reaches out to you through its sales houses and offers the service and satisfaction that is assured by its 100% standard of quality and service.

To be able to turn to an institution that dominates its field in the industrial world is to safeguard the character of the merchandise you buy. To deal with an organizationthat is doing business at your very door puts upon the man you know that "responsibility which is the conscience of business."

Every one of these 15 offices has been established to bring to you the full advantages and benefit that have made The Canadian Fairbanks-Morse Co. Limited a national institution. Here in these offices is offered everything mechanical that your business requires — they centralize your purchasing—group your orders—bulk your shipments and send but one invoice. And when you buy from The Canadian Fairbanks-Morse Co. Limited you are guaranteed the 100% standard of quality and service in product and organization.

Make our nearest office your buying centre—our catalogue is your buying guide —our 100% quality seal your guarantee.

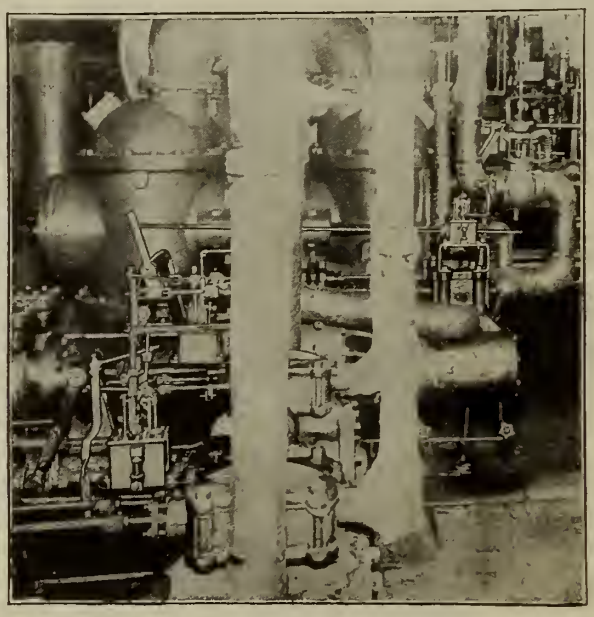
feed in summer. The only way to avoid dust clogging was to place the oil in a solid box free from the working parts. This principle, as soon as discovered, was applied in the most advanced type of pumps. In this way it was made absolutely impossible for flying dust and grit to get into the oil and be carried to the bearings.

Although accuracy and reliability of action were probably the chief considerations in the mind of the originator of these pumps, yet they have been found to effect a very great economy in oil, as well as in man power. Some of the pumps are credited with saving from 50 per cent. to 80 per cent. of oil—a not insignificant matter in these days; and



THE LUBRICATOR IN ACTION.

The working parts should be as simple as possible and they must be easily reached and repaired. One model has a one-piece valve which eliminates practically all troubles, for it is obviously impossible for a solid casting to get out of order. All the working parts of this model are on the outside of the oil reservoir, which probably accounts for the absence of repair bills for continuous service.

The sight feed is one of the latest and most important devices added to the force feed lubricators. The sight feed leaves the action of the lubricator visible so that an interruption in the flow of the oil is immediately detected. By its means, also, the engineer can see exactly the quantity of oil going to the various bearings.

The lubricators also have several chambers in the oil reservoirs, as many as required, in fact, and can therefore deliver different oils to different bearings. This is necessary to the life of any machine. Pumps of all sizes are in use, from the very small one-feed pump to the one holding several gallons of oil and delivering by forty feeds. The larger pumps or, as they may be called, pump systems are designed for the location they are to occupy. The lubrication of an entire plant is thus controlled from a central point. The economic advantage of such a system is unquestionable. To such an extent is this recognized that practically all the large power plants and all marine engines are equipped with automatic force feed pumps.

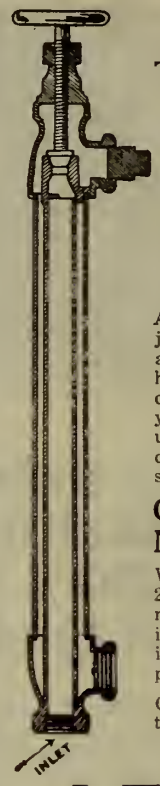
the cost of the wage which would have been paid to an oiler doing the work of its forty feeds.

Recent years may have produced more marvelous and more intricate machines than the force feed lubricator, but none to my mind that have demonstrated a greater usefulness or a more perfect adaptation to the needs they were designed to serve.

The Three Rivers Pulp & Paper Co., Ltd., have awarded the general contract to William I. Bishop, Ltd., Montreal, for the construction of its plant at Three Rivers, Que., to cost with equipment $1,500,000.

A coating of magnesia cement on the timbers of mines is stated to be an economical and efficient assurance against fire, especially in the arid regions where timber becomes highly inflammable and is difficult to replace. It is elastic, adheres firmly to almost any surface, and is stable and durable.

T. W. Lesage, for many years superintendent of the Montreal Water Works, has tendered his resignation to take effect at the beginning of the year. Mr. Lesage entered the services of the city back in 1890 as assistant engineer, advancing from one position to another until he was appointed to the position of superintendent of the aqueduct in 1911. About a year ago he was superseded in his position by Mr. Terrault, and since that time has been acting as consulting engineer for the department.



The LONG Patent Steam Trap

Automatically drains jacket kettles, separators and steam mains. Nine hundred to 1,500 feet of one-inch pipe isn't beyond its ability. Also used with splendid success in drying room systems.

Only One Movable Part

Works against 1 and 200 pounds of pressure—no possibility of freezing. Has **two outlets** so it can be installed in any position.

Circular gives full particulars.

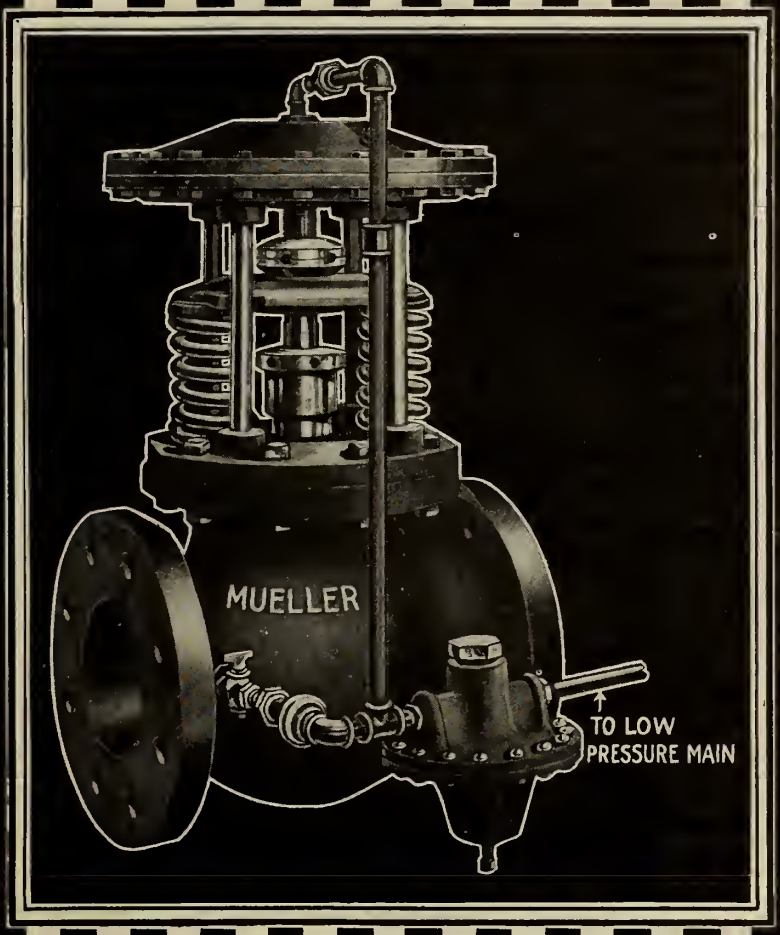
NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 21 & 23 & 24 SOUTH ST. NEW YORK U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.



MUELLER Reducing and Regulating Valves

This valve — No. A-5030 — will make any desired reduction and will maintain a constant delivery pressure regardless of fluctuations in initial pressure. For water, air, steam or oil, it has no equal.

When valves are installed under our supervision, we fully warrant their performance. There is a *MUELLER* stock valve to meet practically every need. Tell us your problems—and we will help solve them.

Construction of Bell Ringing Transformer: R. G. Flavius; 2200 W.; 7 L. D.; p. 448; Oct. 5, 1920.
Electric Generating Apparatus: 600 W.; 1 I.; p. 549; Dec. 20, 1920.

ENGINEER'S INSTRUCTION ARTICLES

Classes for Instruction of Stationary Engineers: 500 W.; p. 12; Jan. 5, 1920.
Principle of Heat and Thermo-Dynamics: T. H. Fenner; 6600 W.; 2 L. D.; p. 31; Jan. 20, 1920.
Laying Out Boiler and Engine Foundations: T. H. Fenner; 1200 W.; 1 L.D.; p. 64; Feb. 5, 1920.
Erecting Boiler and Engine Foundations: T. H. Fenner; 1400 W.; p. 142; Mar. 20, 1920.
The Erection of Engines and Boilers; T. H. Fenner; 1500 W.; 1 L.D.; p. 212; May 5, 1920.
Mathematical Work in Connection With Graded Certificates: T. H. Fenner; 5000 W.; p. 232; May 20, 1920. 5000 W.; p. 261; June 5, 1920. 2600 W.; p. 287; June 20, 1920. 1400 W.; p. 316; July 5, 1920. 2200 W.; 1 L.D.; p. 340; July 20, 1920. 1300 W.; p. 358; Aug. 5, 1920. 1600 W.; p. 384; Aug. 20, 1920. 3400 W.; 3 L.D.; p. 402; Sept. 5, 1920. 1100 W.; 1 L.D.; p. 426; Sept. 20, 1920. 2700 W.; 1 L.D.; p. 444; Oct. 5, 1920. 2600 W.; 2 L.D.; p. 472; Oct. 20, 1920. 1500 W.; 1 L.D.; p. 494; Nov. 5, 1920. 2800 W.; 2 L.D.; 1 T.; p. 509; Nov. 20, 1920. 1250 W.; 1 C.; p. 524; Dec. 5, 1920. 2700 W.; 1 L.D.; p. 543; Dec. 20, 1920.

FUEL

Some Notes on the Utilization of Lignite: 2000 W.; p. 65; Feb. 5, 1920.
Coal Dust as an Explosion Hazard: L. D. Tracy; 1800 W.; p. 71; Feb. 5, 1920.
General Fuel Situation in Canada: Comm. of Conv.; 2600 W.; p. 76; Feb. 20, 1920.
Methods of Storage and the Weathering of Coal: R. June; 2700 W.; p. 113; Mar. 5, 1920.
Possibilities of Pulverized Fuel: W. J. Dick; 2800 W; 3 I.; 1 L.D.; 4 T.; p. 116; Mar. 5, 1920.
Khang-Comparison Between Old and New: Padus; 2500 W.; p. 132; Mar. 20, 1920.
Hand Firing Soft Coal; 800 W.; p. 143; Mar. 20, 1920.
Possibilities of Pulverized Fuel, II.: W. J. Dick; 3000 W.; 1 I.; 2 L. D.; p. 156; Apr. 5, 1920.
How to Use and Operate Combustion Apparatus: 5000 W.; 1 I.; 5 L.D.; p. 162; April 5, 1920.
Alcohol as a Motor Fuel: 220 W.; p. 167; Apr. 5, 1920.
Money Lost Up the Chimney: 450 W.; 1 C.; p. 211; May 5, 1920.
Some Interesting Notes on Fuel Economy: 3200 W.; 1 T.; p. 225; May 20, 1920.
Some Points on the Theory of Combustion: H. B. Gardner; 2500 W.; p. 318; July 5, 1920.
New England Coal Situation: Report; 1000 W.; p. 365; Aug. 5, 1920.
Oil Firing Installations for Land Boilers: G. F. Ward; 1300 W.; p. 447; Oct. 5, 1920.
Selecting Coal by the Microscope: 1350 W.; p. 452; Oct. 5, 1920.
Utilization of Low Grade Peat for Fuel: Prof. Purcell; 3000 W.; 3 C.; p. 457; Oct. 20, 1920.
Alcohol Motor Fuel Research: 325 W.; p. 459; Oct. 20, 1920.
Saving Fuel by Controlling Chimney Losses: F. F. Uehling; 3200 W.; 8 C.; 1 T.; p. 489; Nov. 5, 1920.
Increasing Conduction and Decreasing Fuel Costs: W. R. Van Nortwick; 4800 W.; 2 I.; p. 503; Nov. 20, 1920.
Burning Wet Tan Bark on Mechanical Stokers: T. H. Fenner; 900 W.; 3 I.; p. 519; Dec. 5, 1920.
Regarding the Control of Combustion: T. A. Pebbles; 1500 W.; p. 521; Dec. 5, 1920.
The Petroleum Situation in the Caucasus; 950 W. p. 532; Dec. 5, 1920.
Advantages of Reduced Grate Area: W. T. Casmey; 1000 W.; p. 538; Dec. 20, 1920.
Utilization of Waste Heat Under Boilers: D. S. Jacobs and A. D. Pratt; 4800 W.; p. 539; Dec. 20, 1920.
Transmission of Power by Means of Gas: "Times Engy."; 1800 W.; p. 15; Jan. 5, 1920.
Description of New Large Gas Engine: "Engineer"; 2600 W.; 2 L.D.; p. 307; July 5, 1920.
Gas Production vs. Electrical Generation: 1000 W.; p. 345; July 20, 1920.
Clearance in Gasoline Engines: Query; 400 W.; p. 434; Sept. 20, 1920.
Gas Engine Drive and Turbine Pumps: 2700 W.; 2 I.; 2 L.D.; 1 C.; p. 515; Nov. 20, 1920.

GENERAL

The Transmutation of Energy: C. C. Carris; 3000 W.; 1 T.; p. 13; Jan. 5, 1920.
Experiment Station of the Bureau of Mines: 900 W.; p. 50; Feb. 5, 1920.
Stationary Engineer—His Position and Future: M. B. Watson; 1350 W.; p. 89; Feb. 20, 1920.
How the Locomotive Whistle Came to Life; F. A. McLean; 600 W.; p. 93; Feb. 20, 1920.
Production of Asbestos Increasing: 250 W.; p. 99; Feb. 20, 1920.
Slag Wool for Covering Steam Pipes: 200 W.; p. 141; March 20, 1920.
Storm Warning for Electric Plant: 220 W.; p. 141; March 20, 1920.
Effect of Hydrogen on Iron and Steel: 300 W.; p. 174; April 5, 1920.
Torsional Strength of Shafts: J. S. Watts; 1200 W.; 1 C.; p. 238; May 20, 1920.
Common Sense in Engineering: W. M. McFarland; 3600 W.; p. 353; Aug. 5, 1920.
Color Schemes for Plant Piping: H. L. Wilkinson; 550 W.; p. 373; Aug. 20, 1920.
Common Sense in Engineering: W. M. McFarland; 2300 W.; p. 374; Aug. 20, 1920.
Points to Observe in Purchasing Equipment: A. S. Loiseaux; 3200 W.; 1 I.; p. 419; Sept. 20, 1920.
Report of Committee on Prime Movers: 2700 W.; p. 424; Sept. 20, 1920.
Cement Joints for Cast Iron Water Pipes: G. W. Pracy; 1300 W.; p. 428; Sept. 20, 1920.
Possibilities of Improved Refractory Material: 900 W.; p. 474; Oct. 20, 1920.
Mica and Its Uses: 425 W.; p. 523; Dec. 5, 1920.

HYDRAULICS.

Water Dynamometer Which Simplifies Testing: 2700 W.; 1 I.; 3 L.D.; p. 45; Feb. 5, 1920.
Some Information Regarding Hydraulics: D. A. Hampson; 5000 W.; 11 L.D.; 3 T.; p. 51; Feb. 5, 1920.

Is Your Plant Equipped —to Save Money?

These three prominent industries are unloading, storing, and reclaiming their coal, coke and ashes with the services of only one man and a

Godfrey Conveyor

From 3 to 5 cars are unloaded and stored very easily in one day at an average power and labor cost of 5 to 7 cents per ton.

Demurrage charges, embargoes, excessive labor and handling difficulties are eliminated and equipment is released from sidings promptly.

By substituting grab hooks for the one-ton conveying bucket, Godfrey Conveyors can be adapted to the handling of Baled Materials, Steel Rails, heavy timbers and innumerable other commodities.

The savings will pay for the system in a remarkably short time.

A request for our representative in your territory to estimate cost and savings involves no obligation.

Write for Catalogue.

Godfrey Conveyor Company

127-147 13th St., ELKHART, INDIANA, U.S.A.

Originators, Patentees and Manufacturers of Conveyors operating Gravity-Filled Bottom Dump Bucket over Monorail

Sold in Canada by

INSTRUMENTS

Operating Features of Carbon Dioxide Recorders: 1500 W.: p. 91; Feb. 20, 1920.
Birth and Development of the Barometer: 1200 W.; p. 115; March 5, 1920.
Thermometer Values: W. L. Thompson; p. 131; March 20, 1920.
Novel CO2 Recorder: 850 W.; p. 183; April 20, 1920.
Water Level Indicator for Boilers: 450 W.; 1 I.; 1 L.D.; p. 270; June 5, 1920.
Boiler Room Load Indicator: T. G. Crosse; 800 W.; 2 L.D.; p. 526; Dec. 5, 1920.
New Compensating Heat-Meter: 1100 W.; 1 I.; p. 551; Dec. 20, 1920.

LUBRICATION.

The Needs of Practice: 1600 W.; p. 97; Feb. 20, 1920.
Lubricating Oils (a new theiry): 1200 W.; p. 173; April 5, 1920.
Emergency Measures: J. E. Noble; 225 W.; 1 L.D.; p. 197; April 20, 1920.
Lubrication and the Germ Process: 500 W.; p. 32a; Dec. 5, 1920.

MANAGEMENT.

Power Plant Management—Condensers: R. June; 3500 W.; 4 I.; p. 159; April 5, 1920; 2700 W.; 4 I.; p. 289; June 20. 1920; **Fuel Oil Burners:** 4000 W.; 1 L.D.; 1 C.; p. 349; Aug. 5, 1920; **Feed Water Heaters:** 5000 W; 5 I.; 2 L.D.; p. 395; Sept. 5, 1920; **Boiler Operation:** 3600 W.; 2 I.; 2 L.D.; p. 499; Nov. 20, 1920; 3000 W; 2 C.; 1 T.; p. 533; Dec. 20, 1920.

NEW EQUIPMENT

Anti-Slip Device for Wood Pulleys — Priming Remedies: p. 17; Jan. 5, 1920.
New Armature Winder—Electric Water Heater: p. 42; Jan. 20, 1920.
Steam Jet Ash Conveyor: G. S. Hamilton; 700 W.; 1 I.; 1 L.D.; p. 68; Feb. 5, 1920.
New Electric Rivet Heater — Fulflo Reversing Pump: p. 94; Feb. 20, 1920.
Wheeler Condenser: p. 122; March 5, 1920.
Radial Type Loader: 1000 W.; p. 146; March 20, 1920.
"Safety" Switches: 800 W.; p. 170; April 5, 1920.
New Type of Plug Valve: 500 W.; 1 I.; 1 L.D.; p. 194; April 20, 1920.
Hay's Differential Draft Gear—The Nokut Valve: p. 216; May. 5, 1920.
The Mono CO2 Recorder—Roberts Unit Jacks: p. 243; May 20, 1920.
New Type of Commutator Grinder: W. F. Sutherland; 1350 W.; 4 I.; 1 L.D.; p. 268; June 5, 1920.
Compression Coupling: 400 W.; 1 I.; **New Fire Apparatus:** 400 W.; p. 294; June 20, 1920.
Twyncone Friction Clutch: 200 W.; 2 I.; **Automatic Grease Cup;** 400 W.; 2 I.; **Promet Bearing Metal:** 450 W.; p. 322; July 5, 1920.
Jones Underfeed Stoker; New Balanced Valve: p. 346; July 20, 1920.
Valve Face Grinder; D.C. Series-Wound Motors: p. 366; Aug. 5, 1920.
Reid Ellipsograph; Universal Belt Fasteners: p. 393; Aug. 20, 1920.
Liptak Arch; Staybolt Cutter: p. 411; Sept. 5, 1920.
Small Vacuum Pump: F. A. McLean; **Small Turbo-Generator Set:** p. 431, Sept. 20, 1920.
Pumps for Corrosive Liquids; Tool Stands: p. 454; Oct. 5, 1920.
Flue Cleaning Rattler; Electric CO2 Recorder: p. 478; Oct. 20, 1920.
Automatic Feed Regulator: 3 I.; p. 497; Nov. 5, 1920.
New CO2 Recorder: p. 531; Dec. 5, 1920.
Turbine Furnace: 1350 W.; 2 L.D.; p. 550; Dec. 20, 1920.

OIL ENGINES

Crossley Cold Starting Oil Engine: 2600 W.; 1 I.; 8 L.D.; p. 128; March 20, 1920.
Description of the Busch Sulzer Diesel Engine: 2500 W.; 2 I.; 4 L.D. 1 C.; 1 T.; p. 250; June 5, 1920.
Municipal Authorities Inspect Diesel Engines: 450 W.; p. 281; June 20, 1920.

OPERATOR'S POINT OF VIEW

Corr. re Graded Certificates: 1200 W.; p. 20; Jan. 5, 1920.
Graded Certificates; Home-made Lubricator: A. O. Stone; 225 W.; 1 L.D.; **Should Valves be Set With No Lead:** 500 W.; **Trimming Device for Washers:** J. O. McDonnell; 300 W.; 1 L.D.; p. 43; Jan. 20, 1920.
Graded Certificates; Conservation of Coal: J. S. Kingston; 650 W.; **Technical Press and Other Things:** J. Scott; 800 W.; p. 69; Feb. 5, 1920.
Horse-Power of Engine Flywheel (Query): 1300 W.; p. 90; Feb. 20, 1920.
Graded Certificate Corr.; Telescopic Candlestick: J. O. McDonnell; 350 W.; 1 L.D.; **The Need of Practice;** 1600 W.; p. 97; Feb. 20, 1920.
Graded Certificate Corr.; Anonymous; 600 W.; M. A. Culling; 600 W.; Henry Wright. 700 W.; p. 101; Mar. 5, 1920.
Water Softeners: J. E. Noble; 850 W.; **Correction On Thermodynamic Article; Telescopic Candlestick:** W. Whip; 225 W.; **Valve Reseating Tool:** A. Norgrove; 150 W.; 1 L.D.; p. 124; March 5, 1920.
Graded Certificate Corr.: Cy. Linder; 750 W.; H. Wright; 1200 W.; A. D. Carmichael; 450 W.; 'Wop"; 550 W.; J. E. Noble; 550 W.; p. 125; March 20, 1920.
New Style Trap: J. E. Noble; 300 W.; **Technical vs. Practical Skill:** J. Ellehon; 900 W.; p. 148; March 20, 1920.
Graded Certificates: "Horatio"; 350 W.; W. H. Long; 400 W.; J. E. Noble; 450 W.; p. 171; April 5, 1920.
Noiseless Water Heater: J. Port; 300 W.; 1 L.D.; **Converting a Breast Drill Into a Drill Press:** W. S. Standiford; 500 W.; 3 I.; 3 L.D.; p. 172; April 5, 1920.
Graded Certificates: H. Wright; 1400 W.; J. E. Noble; 500 W.; p. 195; April 20, 1920.
Graded Certificates: H. Wright; 900 W.; J. E. Noble; 900 W.; J. R. M.; 250 W.; p. 219; May 5, 1920.
Ruptured Tube in Water Tube Boiler: 225 W.; **Boiling Point of Ammonia;** 300 W.; W. C. Klotz; p. 368; Aug. 5, 1920.
Copper Gasket Keeps Engine in Operation: W. S. Standiford; 350 W.; p. 143; Sept. 5, 1920.
Building Up a Ligament in a Tube Sheet: R. McLaren; 200 W.; 1 L.D.; **Portable Light Stand:** J. Thorn; 200 W.; 1 L.D.; **Alarm Bell Signals:** J. E. McCormack; 1000 W.; 1 L.D.; p. 433; Sept. 20, 1920.
For Worn Rods: J. James; 250 W.; 1 L.D.; p. 553; Dec. 20, 1920.

POWER PLANTS

Water Powers of British Columbia: Conservation Report: 6700 W.; 6 I.; p. 1; Jan. 5, 1920.
Increase of Power Plant Efficiency: Robt. June; 2000 W.; 2 T.; p. 8; Jan. 5, 1920.
Electrical Energy Generating Stations, I.: Terrel Croft; 2800 W.; 7 L.D.; 5 T.; p. 25; Jan. 20, 1920.
Electrical Energy Generating Stations, II.; Terrel Croft; 3200 W.; 9 L.D.; p. 82; Feb. 20, 1920.
Power Plant Features of a By-Product Coke Oven: W. F. Sutherland; 3600 W.; 15 I.; p. 107; March 5, 1920.
Electrical Energy Generating Stations, III.; Terrel Croft; 3500 W.; 1 I.; 17 L.D.; p. 137; March 20, 1920.
Power Plant Features of the Quaker Oats Mill: W. F. Sutherland; 3000 W.; 11 I.; p. 151; April 5, 1920.
Plant Equipment of a Montreal Dairy: J. H. Rodgers; 2700 W.; 5 I.; p. 175; April 20, 1920.
Electrical Energy Generating Stations, IV.; Terrel Croft; 2500 W.; 38 L.D.; p. 204; May 5, 1920.
Power Plant of the St. Lawrence Sugar Refinery: J. H. Rodgers; 1200 W.; 3 I.; p. 223; May 20, 1920.
Power Plant Features of the Canadian Ford Co.: W. F. Sutherland; 4800 W.; 10 I.; 1 L.D.; p. 301; July 5, 1920.
A 25,000 Horse-Power Mill Engine: 800 W.; 1 I.; p. 405; Sept. 5, 1920.
The Power Plant of a Flour and Salt Mill: T. H. Fenner; 3800 W.; 5 I.; 1 C.; 1 T.; p. 483; Nov. 5, 1920.

PUMPS

Explosion Pump in Irrigation Service: 2700 W.; 1 I.; 3 L.D.; p. 73; Feb. 20, 1920.
Operation of Pump and Injector: Llewellyn; 2500 W.; 4 L.D.; p. 87; Feb. 20, 1920.
Handling Ashes by Centrifugal Pumps: A. Baalack; 425 W.; p. 227; May 20, 1920.
Radojet Air Pump and Its Operation; H. Wright; 2500 W.; 4 L.; p. 254; June 5, 1920.
Air Pumps for Condensing Equipment: F. R. Wheeler; 7000 W.; 8 L.D.; 7 C.; p. 327; July 20, 1920.
Electrically Driven Pumps; 600 W.; p. 15a; Sept. 20, 1920.
Gas Engine Drive and Turbine Pumps: 2700 W.; 2 I.; 2 L.D.; 1 C.; p. 515; Nov. 20, 1920.
Height Hot Water Can Be Lifted: C. C. Warren; 350 W.; p. 553; Dec. 20, 1920.

QUESTION BOX

Horse-Power Query; Graded Certificate Query: p. 123; March 5, 1920.
Hydraulic Test on Small Boilers; Horse-Power of Air Compressor; Size of Steam Header: p. 218; May 5, 1920.
Valve Action of the Corliss Engine: 1000 W.; 2 L.D.; p. 242; May 20, 1920.
Ice Machine Queries: p. 324; July 5, 1920.
Heating Buildings; Superheated Steam for Dyeing and Cleaning Purposes; Reversing Automatic Engine; Size of Chimney: p. 529; Dec. 5, 1920.
Pump or Injector; Dynamo Horse-Power; Bin Capacity; Altering Cut-off; High or Low Pressure; Burning Wood Refuse: p. 548; Dec. 20, 1920.

REFRIGERATION.

The Largest Western Ice Plant: F. C. Perkins; 1300 W.; 3 I.; p. 11; Jan. 5, 1920.
Some Principles Underlying Refrigeration: A. Taylor; 1200 W.; 1 L.D.; p. 106; March 5, 1920.
Explosions in Ammonia Refrigeration Plants: W. C. Klotz; 850 W.; p. 178; April 20, 1920.
Absorption System of Refrigeration: J. F. Patton; 2800 W.; 4 I.; 1 L.D.; p. 179; April 20, 1920.
The Indication of the Ammonia Compressor: F. F. McNeil; 1200 W.; 1 L.D.; 1 T.; p. 182; April 20, 1920.
Synchronous Motor and Refrigerator: W. H. Easton; 1350 W.; 2 I.; p. 187; April 20, 1920.

STEAM AND STEAM ENGINES.

Operating Features of Steam Turbines: 4500 W.; 2 I.; p. 78; Feb. 20, 1920.
Metering of Steam Desirable in Power Plant Operation: 1800 W.; p. 85; Feb. 20, 1920.
The Consulting Engineer in the Steam Plant: F. A. Combe; 850 W.; p. 167; April 5, 1920.
Discussion of the Uniflow Steam Engine: Part I.; H. Pilling; 3000 W.; 2 I.; 5 L.D.; p. 257; June 5, 1920; **Part II.;** 2500 W.; 3 L.D.; 5 C.; p. 276; June 20, 1920.
Some Examples of Economizer Tube Failures: C. E. Stromeyer; 4000 W.; 3 L.D.; 2 T.; p. 282; June 20, 1920.
Simple Low Pressure Steam Control Device: J. W. Smith; 2600 W.; 1 I.; 1 L.D.; p. 437; Oct. 5, 1920.
Advantages of Superheated Steam: 3200 W.; 4 L.D.; 1 C.; p. 460; Oct. 20, 1920.
Steam Engine Development in the Maritimes: D. W. Robb; 1350 W.; p. 467; Oct. 20, 1920.
Geared Turbines for Swedish Battleships: 500 W.; 1 I.; 1 L.D.; p. 469; Oct. 20, 1920.
What is Superheated Steam?: 1800 W.; 1 L.D.; p. 512; Nov. 20, 1920.
Some Points on Turbine Maintenance: 900 W.; p. 526; Dec. 5, 1920.
Safety of Low-pressure Steam Chests: 400 W.; p. 527; Dec. 5, 1920.
Superheated Steam in Stationary Plants: 1000 W.; p. 530; Dec. 5, 1920.

TRANSMISSION

How Many Sizes of Shafting Should We Have?: 850 W.; p. 278; June 20, 1920.
Use of Chain Drive on Grooved Drums: G. H. Roberts; 1400 W.; 1 L.D.; p. 296; June 20, 1920.
Saving in Belt Transmission: "Belts": 450 W. p. 309; July 5, 1920.
Non-Destructive Method of Belt Joining: 350 W.; p. 373; Aug. 20, 1920.
Cone Pulley Belt Shifters: 350 W.; p. 50a; Aug. 20, 1920.
Development of Long Distance Transmission: P. M. Lincoln; 5500 W.; p. 440; Oct. 5, 1920; Part II.; 2300 W.; p. 463; Oct. 20, 1920.

WATER DEVELOPMENT

Water Powers of Canada: 800 W.; p. 10; Jan. 5, 1920.
Some Recent Utilization of Water Power: E. M. Bergstrom; 3500 W.; 5 L.D.; p. 415; Sept. 20, 1920.

WELDING

Autogenous Welding and the Steam Boiler: T. H. Fenner; 2500 W.; 8 I.; p. 134; March 20, 1920.
Recent Development in Oxygen Cutting: 2700 W.; p. 298; June 20, 1920.
Welding Process in the Boiler Industry: A. Malet; 500 W.; p. 334; July 20, 1920.
Interesting Instance of Oxy-Acetylene Welding: 650 W.; 2 I.; p. 418; Sept. 20, 1920.

ELECTRIC WELDING RIVET HEATING

Electric welding has already been applied in Great Britain to the building up of the cutting edge of high speed tools which have become worn or chipped. A later development of electric welding in this connection is provided by a British machine which welds a tip of hard cutting steel on to the shank of the tool. The process takes only a second or two and the weld, which is made under pressure, is the strongest part of the completed tool. This device should appeal to users of machine tools in parts of the world where facilities for repairing tools are not ample.

Another British invention which should appeal to the same class of engineer is a new electric rivet heater. Electricity has been used for this purpose before, but always by way of direct heating in an electrically-heated element. In the new machine the rivet itself forms part of the electrical resistance which generates heat. The tip of the rivet is placed on the machine, completing the circuit. In a second or two it heats up to riveting temperature, the process being so rapid that no scale forms on the metal. As many as two hundred and fifty rivets (half-inch) can be heated in an hour by this machine; and the current consumption is so low that one unit of electricity can heat about 5 pounds of rivets.

HOW TO KILL ANY SOCIETY

We often hear how we can help things along, but it remains for the Michigan Architect and Engineer to tell us how we can kill any society or association.

There are ten ways to kill an association, they say, and here they are.

1. Don't come to the meetings.
2. But if you do come, come late.
3. If the weather doesn't suit you, don't think of coming.
4. If you don't attend a meeting, find fault with the work of the officers and other members.
5. Never accept an office, as it is easier to criticize than to do things.
6. Nevertheless, get sore if you are not appointed on a committee, but if you are, do not attend the committee meetings.
7. If asked by the chairman to give your opinion regarding some important matter, tell him you have nothing to say. After the meeting tell everyone how things ought to be done.
8. Do nothing more than is absolutely necessary, but when other members roll up their sleeves and willingly, unselfishly, use their ability to help matters along, howl that the association is run by a clique.
9. Hold back your dues as long as possible, or don't pay at all.
10. Don't bother about getting new members. "Let George do it!"

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

GOOD INVENTIONS

ENCLOSED LIQUID FUEL COMBUSTION APparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented October 8th, 1918. Can be inspected at and for sale by H. W. Petrie, Limited, 131 Front St. W., Toronto.

EMPLOYMENT DESIRED

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers, Corliss and all classes of stationary engines compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St.

MACHINIST—WITH DRAUGHTING EXPERIence, wants work of any kind. N. Ryckman, No. 174372, 5 Foxley St. Phone Parkdale 3254w. Mention "Power House."

ENGINEER—SEEKS POSITION. ALL ROUND steam and motor experience; British Board of Trade certificate. Apply, mentioning "Power House," to Herdman, 9 Tecumseh St., Brantford, Ont.

RETURNED SOLDIER — EXPERIENCED painter, electrician and elevator operator, or other suitable employment; desires work at once. Apply mentioning "Power House," to Pte. (163466) Ira Charles Winckler, 83 Carlton St., Toronto.

RETURNED SOLDIER WANTS WORK—ANY kind; used to steam heat boilers. Apply, mentioning "Power House," to W. Greenfield (33065), 34 Brock Ave., Toronto.

RETURNED SOLDIER, CHAUFFEUR-MECHanic, must have work. Truck preferred. Reliable, steady, married. Reference. J. Koster, No. 195289. Phone Park. 7758. Mention "Power House."

BELTING

4½—4-PLY NEW CANVAS STITCHED BELTing at 30 cents per foot. We carry a complete stock of belting, pulleys and mill supplies. Apply, mentioning "Power House," to N. Smith, 138 York St., Toronto.

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto.

WE HAVE A QUANTITY OF NEW RUBBER belting to sell at less than half price; will ship C.O.D., subject to inspection; new circular saws, good second-hand leather and rubber belting, wire cable, vises, chain blocks, garden hose, steam hose, rubber packing; send us your requirements; our quotations will surprise. Apply, mentioning "Power House," to The York Belting Co., 115 York St., Toronto, Ont.

SITUATIONS VACANT

WANTED—A1 GENERAL BLACKSMITH FAMiliar with mine and mill work; permanent position. Apply, mentioning "Power House," stating experience and wages wanted, to Moose Mountain, Ltd., Sellwood, Ont.

EQUIPMENT

THE JOHN INGLIS CO., LTD., ENGINEERS and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention "Power House."

WE BUY IDLE EQUIPMENT OR MACHINery; call or write. Apply, mentioning "Power House," to H. W. Petrie, Ltd., Toronto.

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House."

MURPHY AUTOMATIC FURNACES

A Stoker to Meet Your Conditions

The type of Stoker you need is determined by the size of your boilers, fuel, load conditions and other local factors. Naturally, *one* type will not meet all these conditions but in the Riley Underfeed Stoker and Murphy Automatic Furnace you have a choice that will meet practically any condition.

For the plant with large boiler units *or with smaller units that are to be forced above rating* or where reserve capacity is essential, the Riley Underfeed Stoker meets the conditions. The moving grates—found only on the Riley—keep the fuel bed broken up and insure a mixture of air with coal that results in high capacity and efficiency.

For the plant with smaller boiler units or with *medium size boilers carrying a steady load,* the Murphy Automatic Furnace has proved its worth in thousands of installations. Operating on natural draft the original outlay is comparatively small. This furnace requires very little attention and the operator need not be so highly skilled.

The Murphy Furnace is the product of 44 years of investigation and development. With the use of poorer grades of coal in the last few years, improvements have been made to handle such fuel to the best advantage. Many of our clients report highly favorable operation with their old furnaces incorporating these improvements and used with the lower grade fuels.

Since no two plant conditions are alike, it will be to your advantage to utilize the experience of our engineers, who will gladly analyze your power plant problem and recommend the equipment best suited to your needs.

The Findings of Two Authorities
Before and After the Advent of the

COPES SYSTEM
of
BOILER FEED REGULATION

"The advent of the flow meter brings to light the fact that the greatest variations in the amount of work which a boiler does are caused by varying the supply of feed water. To eliminate the fluctuations due to this cause, the feed water regulator at once suggests the desirability of feed water system regulated at each boiler by an automatically controlled valve capable of differential variation according to height of water and rate of steam."

Prime Movers Committee, Nat'l Elec. Light Assoc., June, 1912.

BEFORE the above was printed, the Northern Equipment Co. had foreseen the need, and had been experimenting with a continuous feed regulator which automatically lowered the boiler water level during peak and overloads, and raised it during sub-normal or no load periods. This principle of boiler feed regulation was suggested to the Northern Equipment Co. by the method commonly practiced on locomotives, which increases overload capacity, reduces fuel consumption, and saves considerable effort on the part of the fireman. In spite of the fact that the new Copes regulator was ridiculed by skeptical engineers and by other regulator manufacturers when it first appeared, many leading power station officials were using Copes Regulators by the early part of 1913 and had found that they did everything that was claimed for them. So satisfactory were the results, that the following report was issued:

"Regulators are now available which give a graduated control of the feed water and permit a variation in the water level between any two extremes that may be fixed. The height of the water in the gauge glass, when the water level remains constant, is then some indication of the rate at which the boiler is being worked. This method of feed control enables peak loads of short duration to be carried with a more uniform working of the furnace."

Power Generation Committee Report,
American Elec. Ry. Engrg. Assoc., October, 1913.

A MOST RECENT DEPARTURE

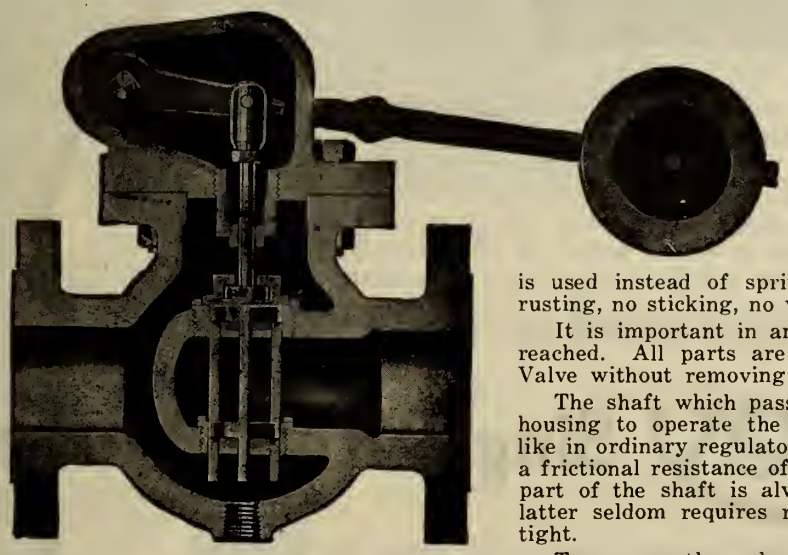
A Boiler Feed Regulator

Specifically Designed To Suit Each Boiler

THE results of a long series of tests and investigations which the Northern Equipment Co. started at the beginning of 1917 are now at the disposal of the engineering profession.

The purpose of these was to determine the actual flow through Copes Control Valves under all the various conditions which determine the characteristics of boiler feed regulation, such as normal boiler horsepower, maximum rating, method of firing, steam pressure, water pressure, and the size of the feed line. With the data now at hand, it is possible to offer a Copes Feed Water Regulator especially designed to insure maximum operating efficiency under any set of conditions peculiar to a given boiler. This can be applied to old installations as well as new ones.

Three general types of Copes Boiler Feed Valves have been carefully developed. The Northern Equipment Co. engineers will furnish a design made to meet the specific requirements governing each boiler.



The Copes Regulator Control Valve

This cross-sectional view shows the perfectly balanced Copes control valve, in which sliding spindles have been entirely eliminated. A weight is used instead of springs, giving constant force. No rusting, no sticking, no weakening with age.

It is important in any valve that parts can be easily reached. All parts are easily removed from the Copes Valve without removing the valve from the feed line.

The shaft which passes through a stuffing box in the housing to operate the valve does not slide in and out like in ordinary regulator valves, but rotates slightly with a frictional resistance of practically zero. Since the same part of the shaft is always within the stuffing box, the latter seldom requires repacking or attention to keep it tight.

To remove the valve seats, a piece of flat stock and any ordinary wrench are the only tools necessary. This, too, can be done without taking the Copes valve out of the feed line.

For complete details get our Bulletin D.

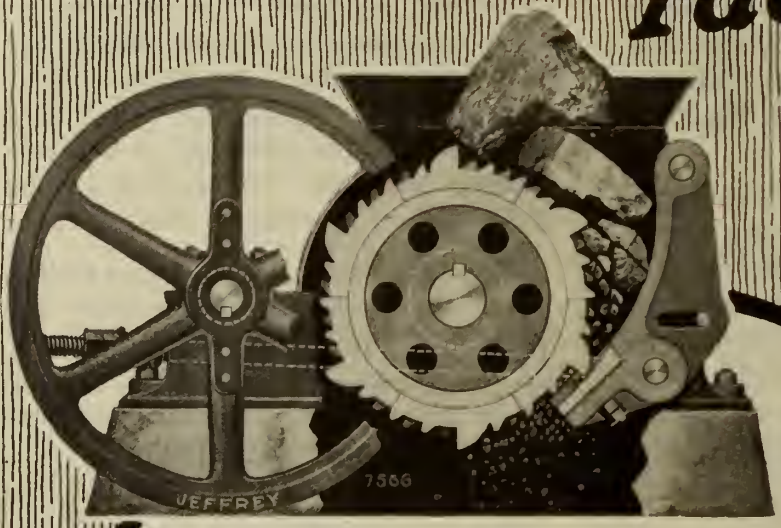
Power plant efficiency = 100% Factor of Safety = ?



PATENTED

Your plant may be functioning at top-notch speed—there may be close co-operation, scientific management, large output, quick deliveries, and everything operating at the highest efficiency, but at the very minute you may be working under a peak load, you suddenly find yourself deprived of a supply of stoker coal and your whole system goes to smash.

Your have overlooked the Factor of Safety.

A Jeffrey Single Roll Crusher

installed in your power plant means a real, lasting and dependable Factor of Safety.

It crushes run-of-mine or lump coal to stoker size in one operation and makes your plant independent of Mine, Weather and Traffic Conditions.

Write to-day for copy of Bulletin No. 141-4.

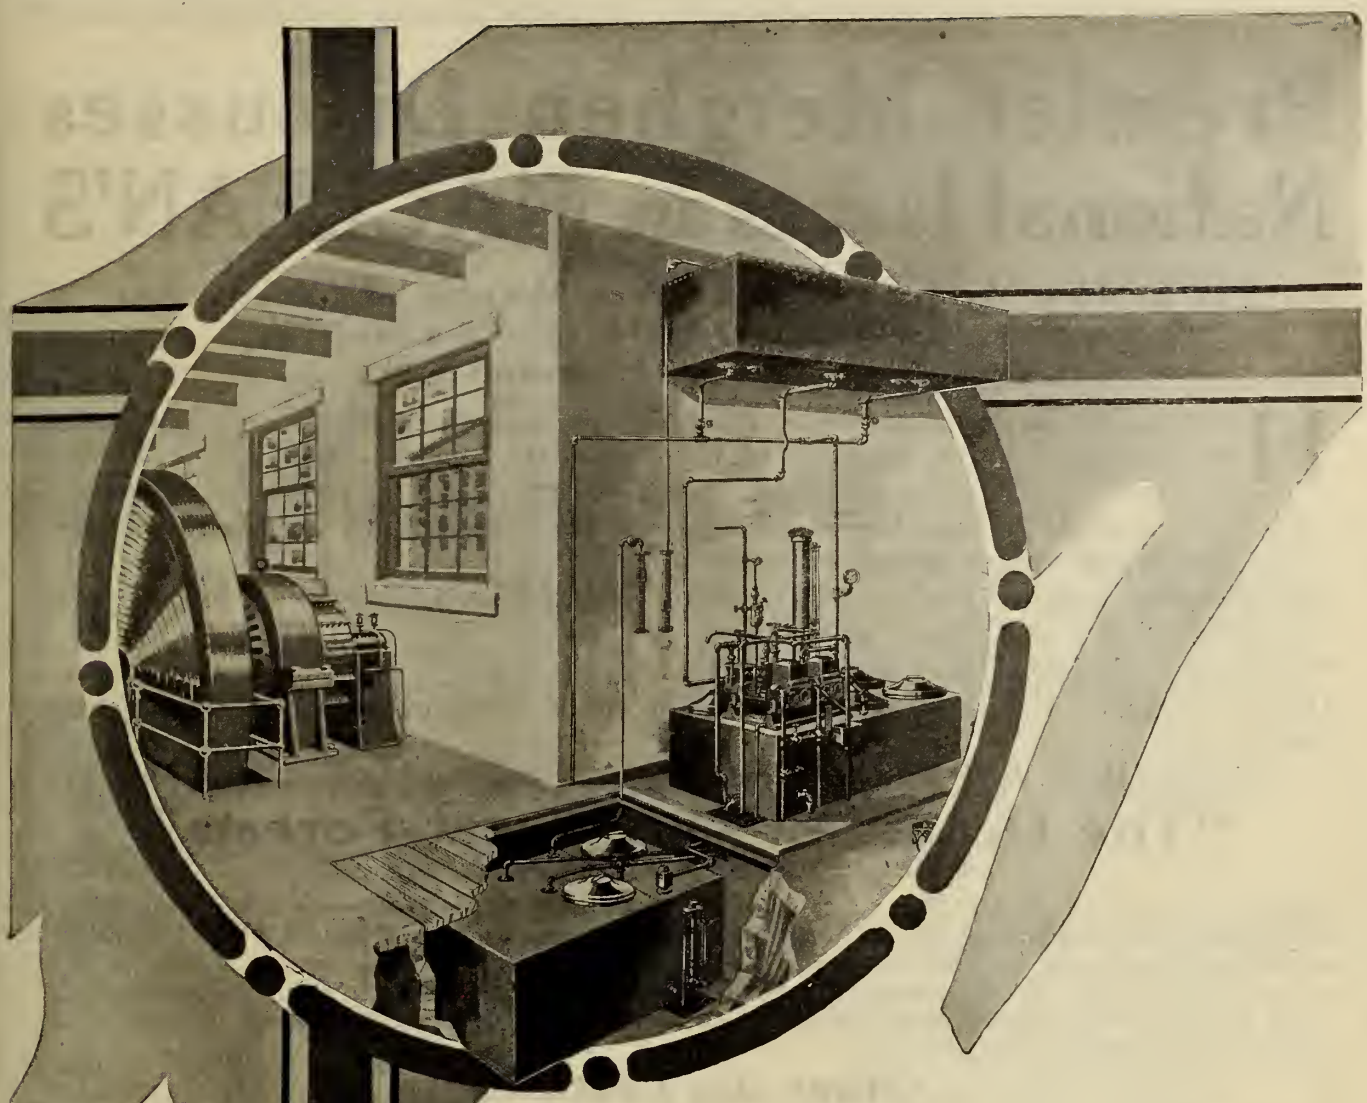
The Jeffrey Mfg. Co.

Canadian Branch and Warerooms

MONTREAL



Save Fuel by Reducing Friction

Much of the friction on engines is due to irregular hand feed lubrication or using oil which is dirty and contains impurities. This increased friction necessitates the consumption of more coal to produce the required power.

Reduce this friction by installing a Bowser Stream Feed Circulating and Filtering System.

A close study of operating costs in power plants has proved conclusively that there is a reduction in friction and a saving of approximately 5 per cent. in the fuel costs where stream feed lubrication is in practice as compared with hand lubrication methods.

In a plant of only ordinary size, a year's saving in the reduced friction will pay for the installation of a Bowser Stream Feed Lubricating and Filtering System.

Write for our illustrative booklet showing our various filtration systems.

Premier Meighen Discusses National Issues in MACLEAN'S

The Rt. Hon. Arthur Meighen, Prime Minister of Canada, has written for January 1st MACLEAN'S a forceful exposition of his platform and policy.

HE discusses the bi-lingual issue, the tariff, reconstruction, the growing unrest and unemployment — but he avers that the tariff is the "one great issue of our domestic politics."

"Why is it the issue?" queries Mr. Meighen. "It is the issue, I think, because the enemies of the Government cannot oppose us on any other."

Regarding the tariff, the Premier tells readers of MACLEAN'S: "We do not propose going any higher *on any single line of articles.*"

"Is Mr. Crerar hedging?" the Premier inquires.

Of Mr. Mackenzie King he says: "He can be quoted on almost every conceivable side of the tariff issue."

Articles by Mr. W. L. Mackenzie King and Mr. T. A. Crerar will follow in succeeding issues.

"The Drama of Our Great Forests"

A BIG INSTALMENT IN JANUARY 1st MACLEAN'S

This stirring story by Arthur Heming is continued in January 1st MacLean's, chock-full of wood-lore, fascinating yarns of the luring, frozen North, and amazing tales of actual adventure. The life history of the Canadian beaver, our national animal, is unfolded in a manner that surpasses fiction, as fact so often does if truly told by a masterful writer—"the beavers—those wonderful amphibious animals of the Northland that display more intelligence, perseverance, prudence and morality than many a highly civilized human being."

Other Big Features

"The Big Time Man."
By C. W. Stephens.
A romantic story of the unromantic business of making bottles.

"Money and Motion Pictures."
By John W. McKay.
A Canadian who filmed "The Miracle Man."

"The Diamond Pickers."
By Madge MacBeth.
The girl detective finds how diamonds disappear by extra-human agency.

"Foiling the 'Free Trader'."
By Kathrene and Robert Pinkerton.
A Hudson's Bay story, where the Indian outwits his white foe.

"The City of Peril."
By Arthur Stringer.
A big slice of this serial of Bolshevistic peril.

"When Toronto Grew Up"
By Col. Geo. H. Ham.
Anecdote after anecdote of the past fifty years in Toronto.

"Margot and Peter Flower."
By Mrs. "Margot" Asquith.
The commencement and course of an amazing eight years' flirtation.

Foresight in Selecting Rubber Hose

Most buyers of rubber hose know from experience the dependability of Dominion Rubber System Hose in living up to every claim made for it.

We meet the demands of modern industrials by making over fifty types of hose to meet every condition, simple or exacting as it may be.

Dominion Rubber System Hose for Every Industrial Use

is made in various types, for liquids, oils, gas, acids, steam, suction and other uses, at all practical pressures and temperatures.

With our comprehensive catalogue before you, it is an easy matter to specify the particular hose for any requirement.

For catalogue or information, write our nearest service branch.

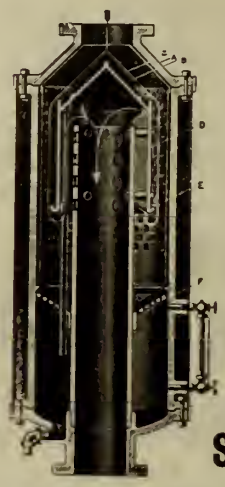
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

WEIR PUMPS

The Most Reliable For Feed and Other Duties

The boiler is the heart of the ship or power plant. Any possibility of a stoppage is exceedingly serious. Therefore it pays to use pumps whose past and present performance proves that they are to be relied upon at all times.

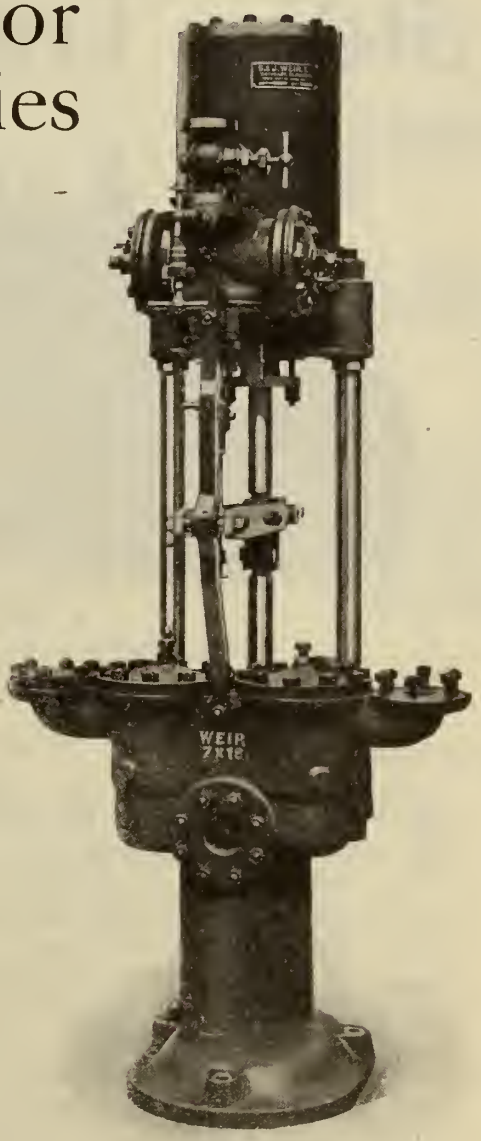
Weir Pumps are designed to work at moderate speeds. Thus they last longer and work more satisfactorily than high-speed running pumps.

When you buy a Weir pump you are sure of quick service in case new parts are required.

Overhauling and renewal is greatly facilitated by our system of interchangeable parts and the fact that we keep in stock at all times parts for our standard pumps.

Special attention is paid to the prompt dispatch of goods and the routing and shipment of all consignments. Special instructions in this regard always receive our most careful attention.

The fact that there are over 65,000 Weir Pumps in use in all parts of the world should be proof positive of the service they render.



Full particulars of Weir Pumps and other auxiliaries will gladly be furnished upon request.

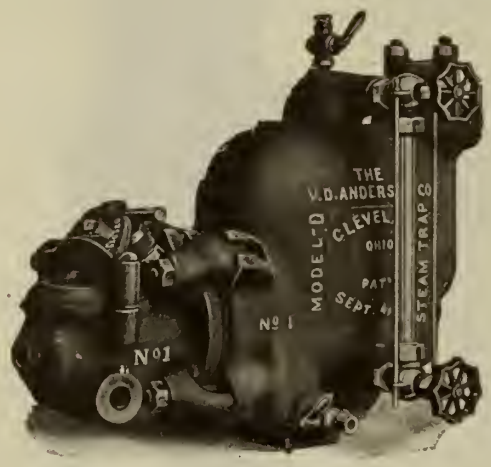
ANDERSON
Model "D"
Steam Trap



No More Condensation Worries ! !

THE shortest route to absolute freedom from expense and numerous condensation worries is to install an Anderson Model "D" Steam Trap in your steam room. Think of the carefree trap service it will give you—tight from the moment it is installed.

The Anderson, by reason of its interchangeable parts, can be used on any steam apparatus where there is condensation to handle. Its sturdy construction and simple design give complete accessibility to every part.

If it can save fuel for these and scores of other leading companies, it can save fuel for you.
The New Uehling CO2 Equipment reduces waste of fuel up the chimney by insuring correct air supply. It guides the fireman at the boiler in burning any kind of fuel, while simultaneously recording results in the chief engineer's office. It usually pays for itself in a few months, or even weeks, by savings effected.
Send for Bulletin 111
CO2 Indicator is as important to combustion economy as the water gauge glass is to safety. Mounted on the boiler front, it guides the fireman by showing the percentage of CO2 and giving warning when improper furnace conditions prevail

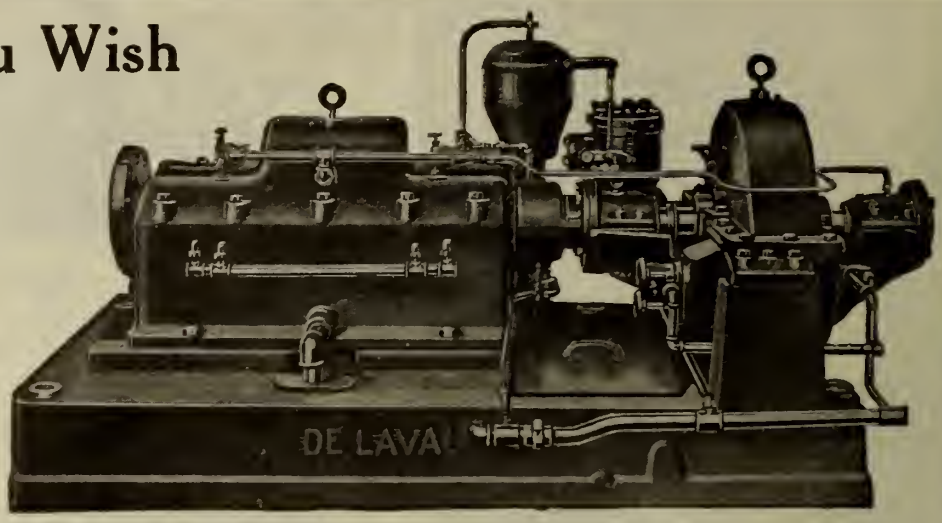
What Do You Wish To Drive?



THIS DE LAVAL GEARED TURBINE can be directly connected to shafting, belt pulley or rope sheave, standard-speed electric generator, large centrifugal pump or blower, rolling mill, paper machine, or any apparatus running at moderate speed.

It is simple, has few parts and is substantially built. The forced lubrication system with sight feed eliminates the oil can and the grease cup and the man who takes care of them. The hand-operated nozzle valves provide for maintaining efficiency with widely varying loads or steam pressures. The powerful, accurate governor gives close speed regulation.

This particular turbine is designed for non-condensing service, the exhaust to be used for industrial purposes.

De Laval steam turbines are built for all steam conditions and for driving all kinds of machinery.

If you will state your requirements we shall be glad to send appropriate literature, together with detailed information. Ask for Booklet C-1.

No Weakness At Any Point

Our thorough knowledge of Valves and Valve requirements has taught us the value of correct proportion and proper distribution of metal.

Such knowledge, acquired through some 56 years of practical manufacturing experience, means just this to the purchaser of valves—that every valve bearing our Trade Mark (the name "Jenkins" within a Diamond, cast on the body) is **designed and proportioned for the maximum service**, that it is safe and dependable under all conditions, and that there is no weakness at any point.

And the line is complete—a Valve for Every Service—Every one tested before leaving the factory.

Supply houses everywhere carry the complete Jenkins line. When buying or specifying valves insist upon the **genuine** Jenkins—known by the Diamond Trade Mark.

Write for Catalog No. 8.

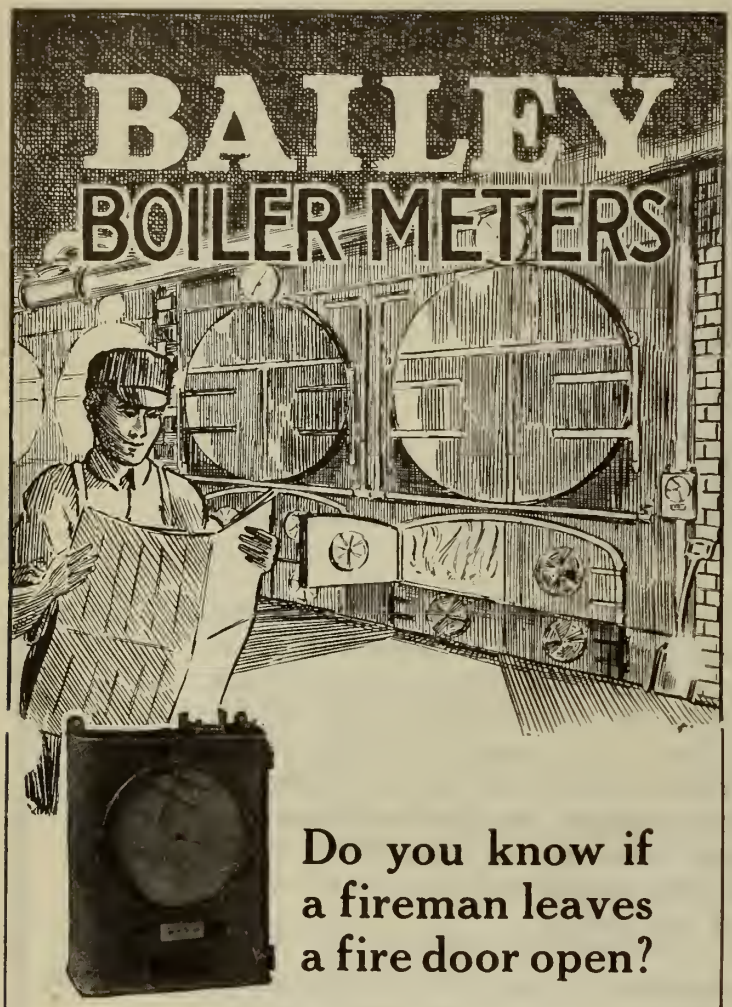
BAILEY BOILER METERS



Do you know if a fireman leaves a fire door open?

Should your steam pressure drop suddenly would you be able to locate the cause with certainty? Bailey Boiler Meters would enable you to.

To the engineer the chart records of Bailey Boiler Meters show the performance and condition of each boiler. He can tell the presence of leaking tubes, broken-down baffles, dirty tubes, defective settings, leaking blow-offs, improper feeding, or negligence of any sort on the part of the firemen. The charts are a positively dependable record of the boiler room results obtained each day.

Let us help you get the most from your coal. Write to-day for a copy of our bulletin.

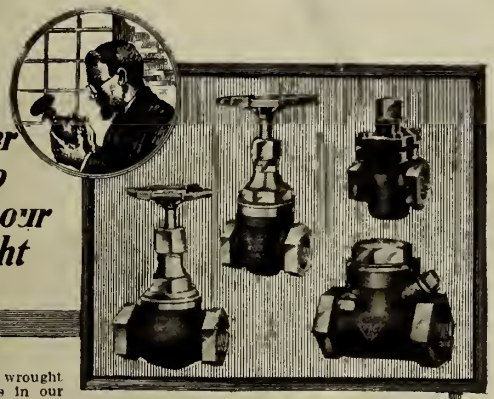
In Cotton Tubes

STEEL MILL PACKING CO., WINDSOR, ONT.

We have never grown too big to do our Work Right



Time has wrought great changes in our plant since the days when Rufus Pratt, a master mechanic of the old school, began to make valves in a diminutive factory in Hartford. But one thing has never changed—**the principle of adhering to high standards.**

Carefully cast, to insure proper thickness of the walls; accurately machined; each part true to gauge, and carefully inspected, a Pratt & Cady Valve of 1920 measures up to the same standards of high quality as a Pratt & Cady Valve of 1870.

Pratt & Cady Valves are made in all types—Angle, Back Pressure, Blow-off, Check, Cross, Gate, Globe, Split Wedge, Water Gate, etc.—in iron, steel and bronze, for every kind of service.

50 Carloads of Coal Saved

ELESCO
SUPERHEATERS SAVE FUEL

In a plant operating under a load of 5,000 k.w., 24 hours, 2,100 tons or 50 carloads of coal are saved a year by superheating. With coal at $6.00 a ton, Elesco Superheaters would save $12,600.

EVERY 7th DAY A WHOLE CAR LOAD SAVED!

and this represents a saving of only 10%. In smaller plants a higher percentage saving than this is the rule rather than the exception—often a saving of 20% is realized. Elesco Superheaters effect such worth-while savings. In new or existing plants they are applied without changes to boiler settings.

Valuable data is found in our Bulletins T-5 and T-6

Money-Saving Information

"The most useful information contained in any paper I get"—so a Western banker writes in to-day's mail, renewing his subscription for FINANCIAL POST.

"Very often," his letter goes on to say, "I am called on to suggest investments for small amounts, sometimes as low as a few hundreds, and I find your Investors' Inquiry Service a reliable partner to consult. If every investor knew there was such service at his call it would surely lessen the losses of many of these people."

The Investors' Inquiry Service fills just that need. Unless you are perfectly sure of your investments write us before you buy.

It costs FINANCIAL POST subscribers nothing to be sure before placing hard-earned savings in stocks that may never have a chance of paying dividends. Trained service men will give you the benefit of keen analysis based on the facts behind the securities you are considering. This is one of many features enjoyed by our readers.

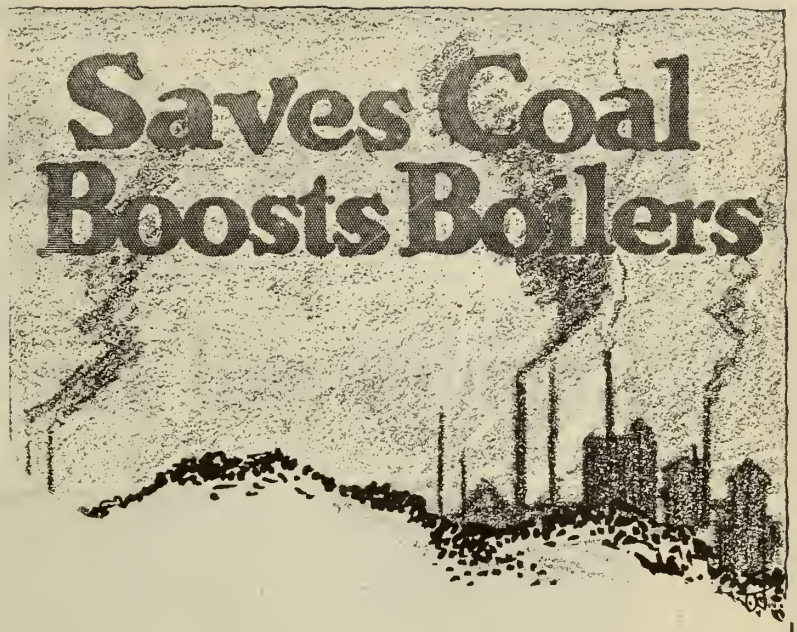
The Hays Automatic CO_2 & Draft Recorder Awarded Certificate of Merit by the Franklin Institute.



Efficient Combustion under your boilers will save tons of coal each day. Much of the loss in fuel is due to the ignorance of the importance of air or draft. To maintain efficient combustion in your boiler-room it is necessary that your firemen have accurate information regarding the fires.

The Hays Automatic CO_2 & Draft Recorder will show your firemen when the boilers are wasting coal so that they can check the loss instantly. Hays Recorders guide the firemen in the right way by timely information about the fires, thus enabling them to regulate the draft and thickness of fuel bed so that the highest percentage of CO_2 may be maintained.

Let us give you a few facts on the importance of combustion efficiency in your boiler-room.

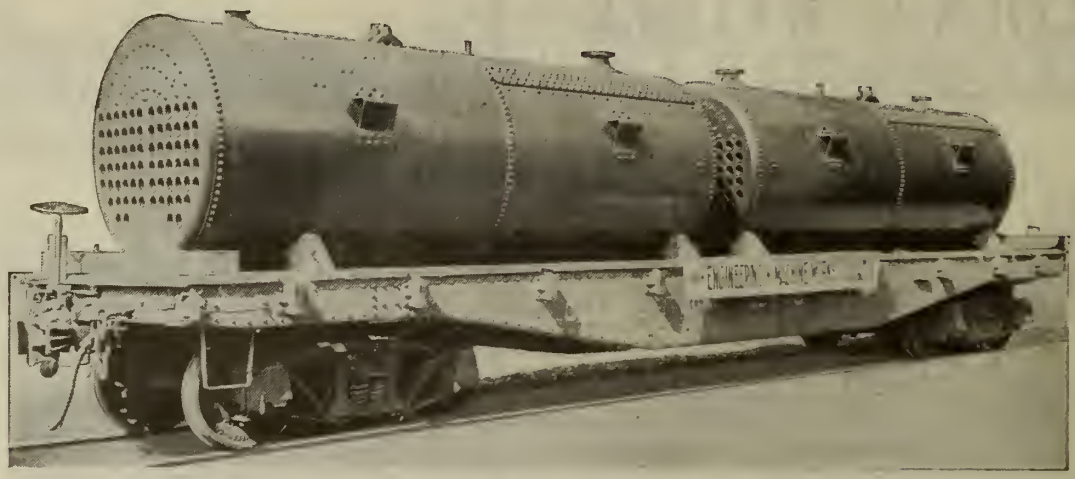
Toronto—A. G. Milton, 32 Front St. West



NO SENSIBLE MAN

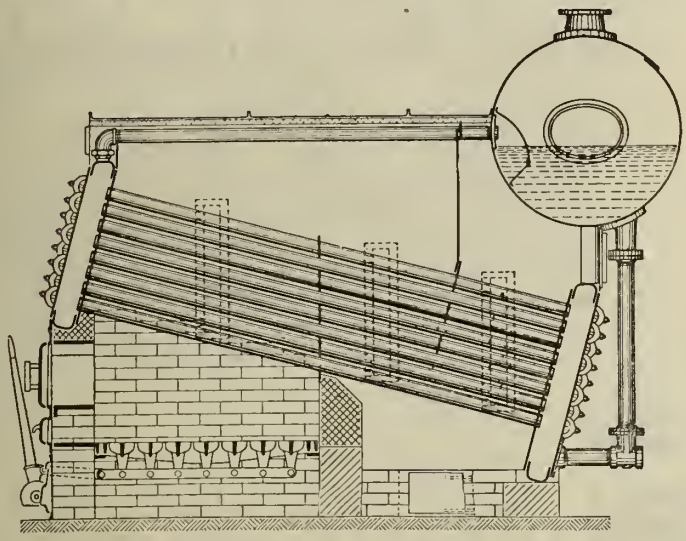
expects the present so-called business depression to continue indefinitely. Canada's position in all fundamentals is too strong to allow anything but a very temporary slowing up in our strides towards national greatness. The wise manufacturer will take this opportunity to set his house in order. We are particularly interested in your steam plant. We say in all seriousness—now is the time to order new boiler equipment. We are in splendid shape to serve you.

Engineering & Machine Works of Canada, Limited

ST. CATHARINES, ONT.

Eastern Sales Offices: Hall Machinery Co., Sherbrooke, and Birks Bldg., Montreal

The Victory Heating Boiler



Is a water-tube boiler designed for heating, and is the safest boiler that can be used.

It has a steel case lined with asbestos and firebrick and requires no brick setting.

It may be shipped knocked down and taken into a building through ordinary doors.

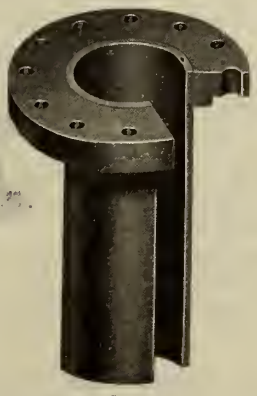
P⌀H FLANGED PIPE JOINTS



SCREWED

P.H. LAP

P H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

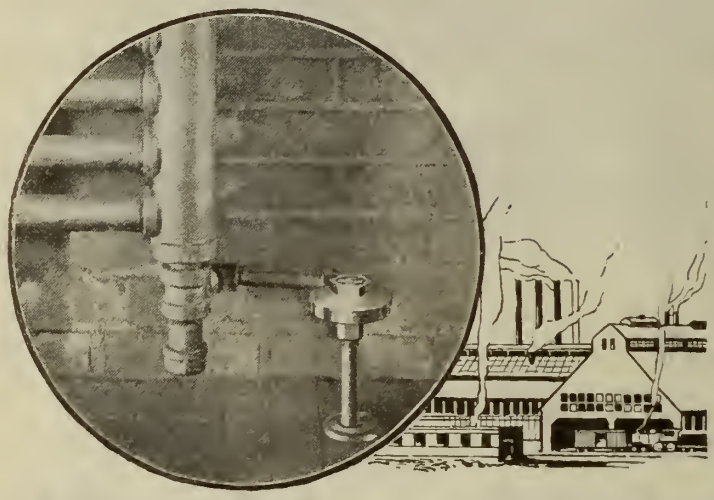
MADE IN CANADA BY

PAGE-HERSEY TUBES, LIMITED

Head Office: **100 Church Street, TORONTO, Ont.**

MADE IN CANADA

The *Smallest Part* of a Steam Heating System is the Most Important



The Dunham Radiator Tap

IT'S the smallest part of your steam system—the Radiator Trap—that sometimes proves the most expensive. If your trap is inefficient, steam is leaking back into the system. This means wasted fuel and money. Dunham Radiator Traps cannot leak and therefore conserve steam and fuel. Besides saving fuel they put pep into lazy radiators by keeping them hot **all over.**

For proof, ask for our new Bulletin 110, "The Dunham Vacuum Heating System." Send us the boss's name. He will find it interesting, too.

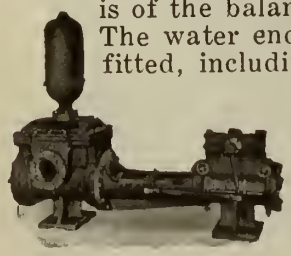
AMERICAN-MARSH PUMPS

SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.

The line also includes—
Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

ECONOMY *renewable* FUSES

Knife-blade type Economy Fuse

Industries persisting in the use of "one-time" fuses pay more for electrical protection than those equipped with Economy Fuses.

The famous Economy "Drop Out" Renewal Link makes possible an annual saving of 80% in fuse maintenance costs.

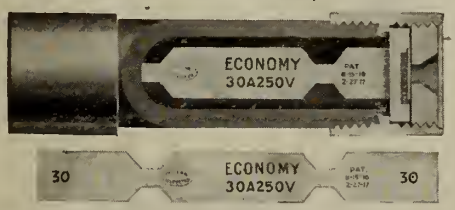
Nothing is destroyed when an Economy Fuse blows but the inexpensive strip of fusible metal.

This is quickly and easily replaced with a new "Drop Out" Renewal Link without delay to men or machinery. The heavy cartridge, end caps and the winged washers which lock the fuse are virtually indestructible and are used again and again.

Check up fuse costs in your plant. And remember that Economy Fuses give maximum protection at minimum cost.

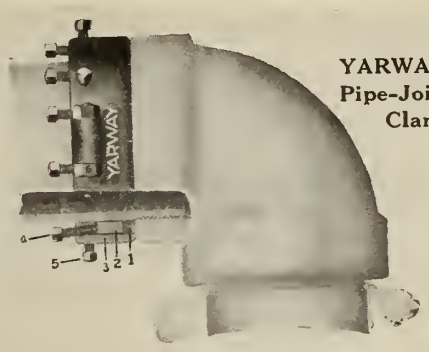
For sale by all leading electrical jobbers and dealers.

Economy Fuse & Mfg. Co. of Canada, Ltd.
UNITY BLDG., MONTREAL, CANADA



Ferrule type Fuses with Economy "Drop Out" Renewal Link

Economy Fuses were the first line using inexpensive bare links for restoring blown fuses to their original efficiency to be APPROVED IN ALL CAPACITIES by the Underwriter's Laboratories.



YARWAY Pipe-Joint Clamp

Description—1. Square packing ring, forced against leaky joint. 2. Inside ring, forced against packing 1 by screws 4. 3. Outside ring, bolted around pipe by bolts 6, secured by set screws 5, prevents slipping when adjusting screws 4.

The Best Insurance Against Leak Losses

With a Yarway Pipe Clamp, one workman can stop most any steam-line leak, large or small—stop it permanently and in less than ten minutes.

Any leak in your steam lines, whatever its size, is a serious matter with coal at its present prices. Yet the cost of a shut-down to replace the damaged section of pipe is even more serious.

Perhaps, in order not to interfere with production, you are overlooking the leaks—and paying the increased coal bills. But if you could have these leaks completely and permanently repaired in a few minutes, with no interference to work, wouldn't you rather save your coal?

YARWAY

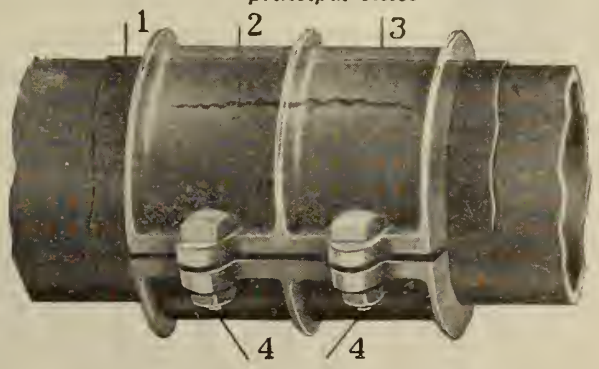
Pipe Clamps

The Yarway Pipe-Joint Clamp stops leaky joints. The Yarway Holtite Pipe Clamp stops holes and splits in straight pipe. Both are stocked in all the usual sizes for immediate shipment.

A supply of Yarway Pipe Clamps on hand is the best possible insurance against leak losses. We'll be glad to send you one to test, without obligation. Write for Bulletin No. C-805, and see what users say about them.

Yarnall-Waring Company
7604-20 Queen St.
Chestnut Hill Philadelphia

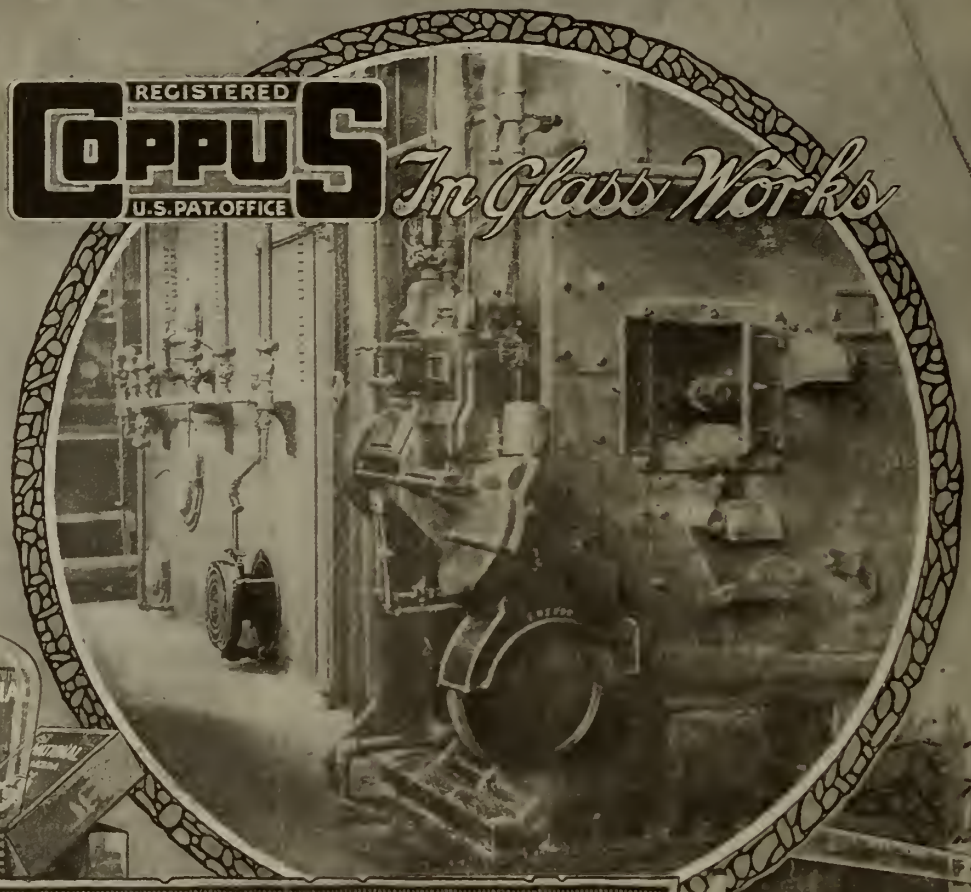
Carried in stock by dealers in thirty principal cities



Yarway Holtite Pipe Clamp

Packing (1) is placed over hole or split (2) in pipe; metal clamp (3) is then placed over packing and around pipe; bolts (4) tighten clamp and hold it in place.

REGISTERED
COPPUS
U.S.PAT.OFFICE
In Glass Works



In the Glass Division Power Plant of the National Lamp Works out in Cleveland, Ohio, they burn gas coal screenings and producer tar difficult fuel to burn economically. Yet with the 4-18" COPPUS Turbo Blowers which they operate, full steam pressure is maintained in their 4-250 H.P. Stirling Boilers and cheap fuel is efficiently burned. Without these Blowers, one of which is shown above, additional boilers would have been necessary last fall. With their aid, however, the heavy plant load is easily handled.

Before the National Lamp Works installed COPPUS Blowers a careful investigation satisfied them that for efficient operation, low steam consumption, and sturdy dependability, COPPUS Blowers stand in a class by themselves. And after practical proof that COPPUS Blowers are all that is claimed for them. Mr. Bretz, Plant Superintendent, expresses himself as "highly pleased with them." In the National Lamp Works, as in thousands of plants in every industry, COPPUS Blowers have proved profitable investments.

Why not find out exactly how and why "COPPUS EQUIPMENT CAN SAVE YOU MONEY?" Write us and our engineers will help you solve your combustion problems. If you haven't a copy of Blower Catalog write for one to-day.

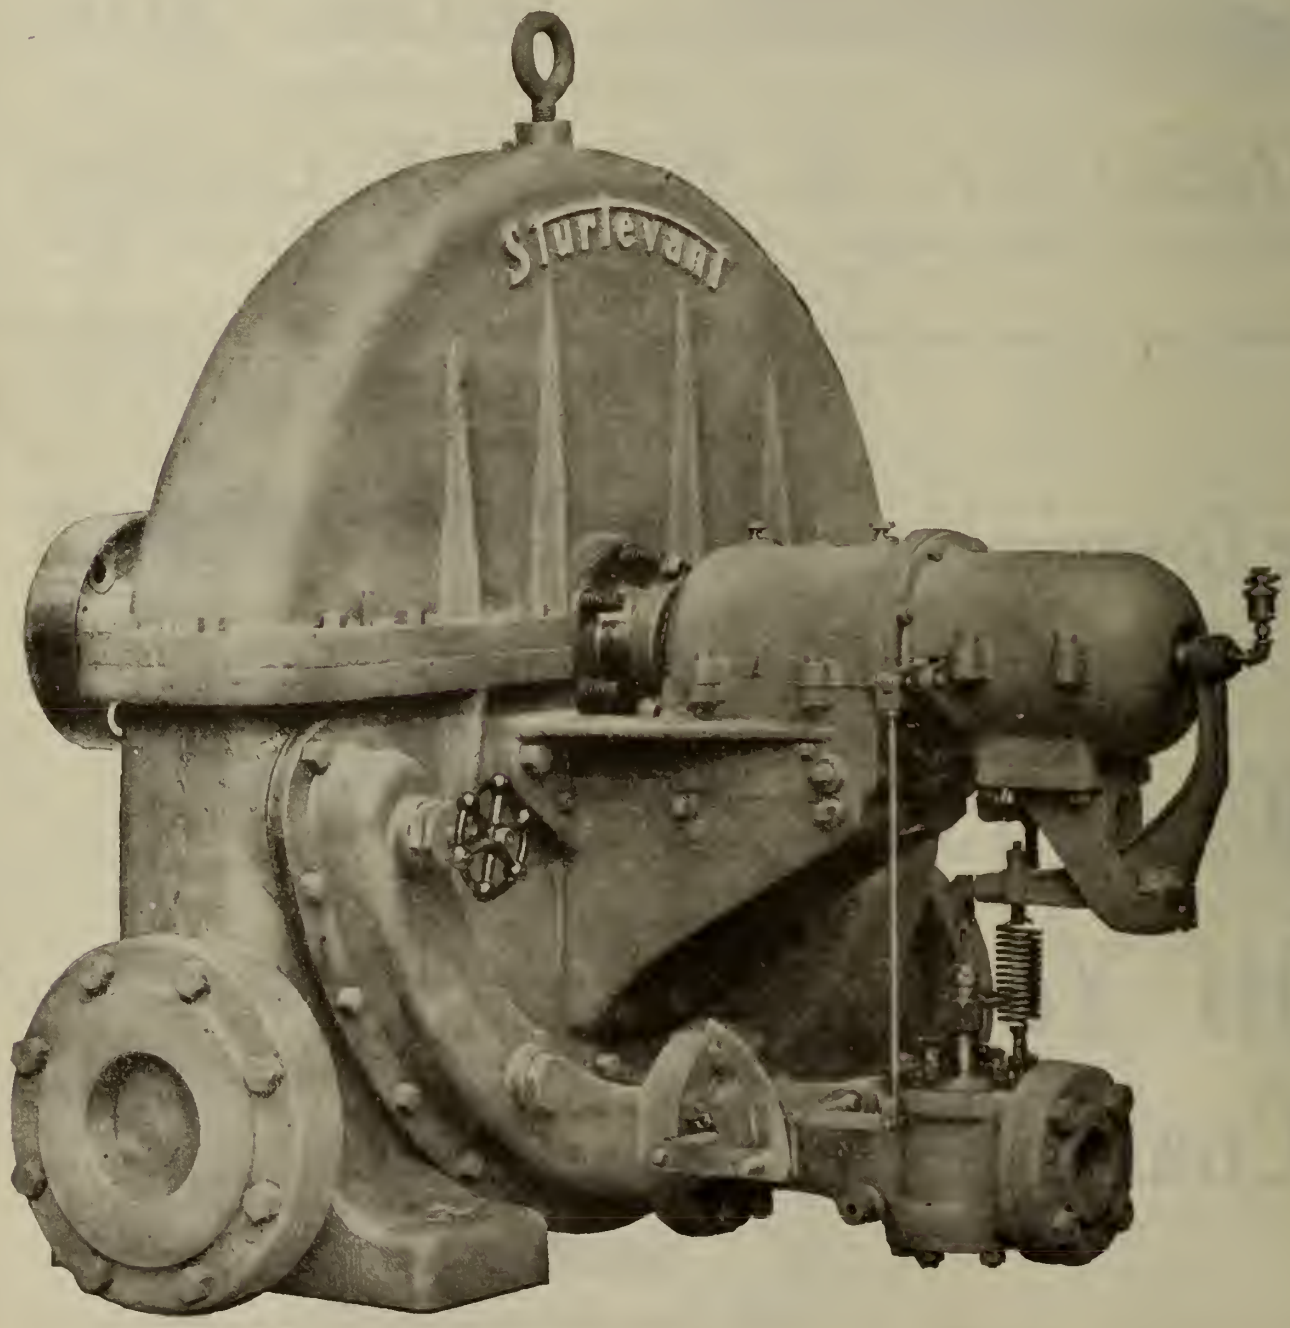
GREEN'S ECONOMISER, LIMITED.
TORONTO

High Economy at

THE objection of high auxiliary steam consumption during the off-load periods in driving exciters, generators, pumps, fans, etc., has been entirely removed in the Sturtevant Turbine due to the individual nozzle valves.



Fractional Loads

One or more of these nozzle valves may be closed by hand as the load drops off, enabling the

Sturtevant

(Trade Mark)

Steam Turbine

to be operated with practically the same economy as normal load.

This feature is of great importance where the demand for power is subject to wide variations.

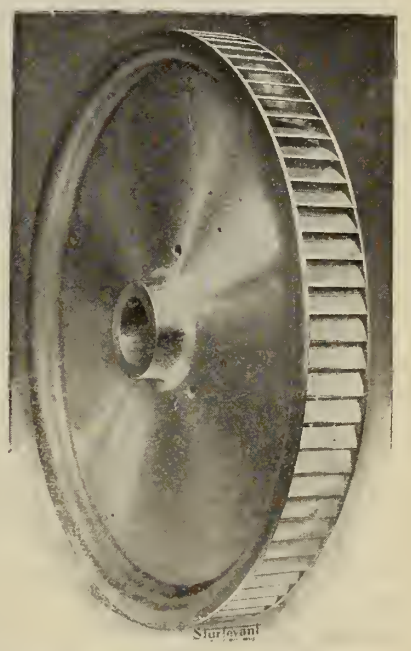
The nozzles and reverse buckets are scientifically designed to impart the maximum velocity to the steam and to permit this to be efficiently absorbed in the rotor.

Close regulation is maintained by a centrifugal governor, which controls the steam admission through a balanced throttle.

The rotor is made of a solid open hearth steel forging, with the buckets accurately milled at the most efficient angle.

Our engineering department has interesting data to present on Sturtevant Turbine drives applied to your plant requirements.

Write for Catalog No. 256 P.



Sturtevant Turbine Rotor.

Durable

NORWALK AIR & GAS COMPRESSORS

When you install an air or gas compressor you take it for granted that you are covering your needs for years to come.

Right enough. Be sure that you do. Select a Norwalk Compressor—whatever the form of service may be—and you can depend on long life for the machine as well as operating efficiency. Norwalk Compressors are internationally known for durability, which results from simplicity of design and high-grade materials and workmanship.

You ought to have the Norwalk Bulletins. Write for them.

THE NORWALK IRON WORKS COMPANY

Pioneer Builders of Compressors

South Norwalk, Conn.

A. S. Leitch Company, Toronto
Canadian Sales Representatives

UPRIGHT BOILER WITH EXTENSION SHELL

We make the following types of Boilers:

Connelly Water Tube
(Patented U.S. and Canada)
Return Tubular
Locomotive
Upright

We specialize in the making of

Smoke Stacks
Tanks of all Types
Plate work of any description
Grey Iron Castings

Head Office and Works: LONDON, CANADA

Clean Boilers
Mean Greater Profits

Consider your boiler room as a factory—a place where steam is manufactured. You can produce steam wastefully or economically as you prefer. The choice lies in your own hands, for success is primarily dependent upon the degree of attention you accord your boilers.

This is true because the principles of efficient combustion of coal and economical boiler operation can be learned by any plant executive in a few hours.

One of the fundamental principles is that a dirty boiler is a costly one. You cannot transmit heat anywhere near as efficiently through a soot-coated boiler tube as through a clean one. Soot is indeed the best heat insulator known. A coating of 1/16" thick applied to every tube would reduce your boiler efficiency nearly 10 per cent.

Boilers can only be cleaned efficiently by Diamond Soot Blowers. With Diamonds every particle of soot is removed at frequent intervals. As compared to the best results obtained by hand cleaning, Diamond Soot Blowers will:

1. Save 4 to 8 per cent. fuel.
2. Increase overall boiler efficiency 2 to 4 per cent.
3. Decrease cost by hand cleaning 90 per cent.

Every day you defer the installation of Diamond Soot Blowers you incur needless losses. On millions of horsepower of boilers, Diamonds are now saving their entire cost two or three times over each year—thus earning 200 to 300 per cent. dividends.

Ask for Bulletin 280

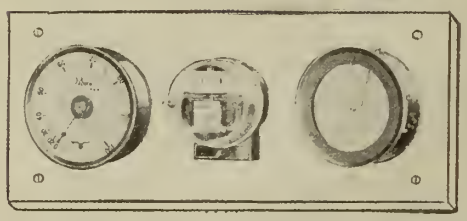
Republic

FLOW METERS



If you do not have an accurate record of your plant conditions, Republic Flow Meters will prove an excellent investment. You cannot better your plant conditions until you have the means of knowing what your plant conditions are.

The Republic Flow Meter is equipped with three reading instruments: indicating, integrating and graphic recording. Electrical operation, an exclusive feature, permits of grouping the instruments on a conveniently located central board and no point is inaccessible to the Republic system—a flexibility that is impossible in any other system.

While you are investigating Republic Flow Meters it will pay you to consider the value of Republic CO_2 Recorders in your plant. They form an unequalled combination for the promotion of greater economy and higher efficiency. Write to us now!

Service that Saves

Coal is deposited direct on pile

Monorail I-beam Installation. Cableway Installation may also be used.

1921 Will Bring Profits With a Godfrey Conveyor

Investment of January funds in a Godfrey Conveyor will pay big dividends and the savings will pay for its cost in a remarkably short time.

1. Save from 40c to 75c per ton on unloading and storing costs.
2. Eliminate demurrage charges by releasing cars promptly.
3. Save salaries paid to shovelers, for only one man is needed to operate with a "Godfrey."
4. Eliminate waste from breakage, for the Godfrey Bucket deposits coal direct on the pile.
5. Reclaim from storage with speed.
6. Added profits will result.

By substituting grab hooks for the conveying bucket, the same system can be adapted to handle timbers, steel, baled materials and innumerable other commodities.

GENUINE OAK

GENUINE OAK

What of the Belting You Depend Upon?

Is the service which it gives all you wish for? A belt may transmit power at a loss of 10, 20 or even 30 per cent. and be considered a fairly good belt. But—why lose 20 or 30 per cent. of your power when D. K. McLaren's Genuine British Oak Tanned Leather Belting would hold your loss to less than 3 per cent.?

Minimum stretch, minimum slippage and fewer breaks are the results you can expect—and get—from D. K. McLaren's Belting.

D. K. McLaren's Leather Belting is made exclusively from close-trimmed butts of the finest selected hides, tanned by the Genuine British Oak Method until extremely tough and pliant.

D. K. McLaren's Leather Belting is as nearly stretchless as a belting should be.

Worthington satisfies every power plant pumping need

IMMENSE shop facilities, standardized manufacturing plus over 81 years of designing, improving and manufacturing pumps and pumping machinery have resulted in apparatus of suitable design for every power plant pumping duty.

This broad range and varied choice of apparatus together with over 200,000,000 boiler horse power successfully satisfied since 1840 justifies specifying Worthington for power plant apparatus. The Worthington engineering corps always stand ready to co-operate in order to obtain greatest possible results from apparatus selected.

Every power user should read this book

The low cost of fuel oil for power, coupled with the time-proven dependability of the Giant Oil Engine is enabling power users everywhere to adopt oil as their standard fuel, and Giant Oil Engines their standard prime movers for operation on it. The book, "Giant Semi-Diesel Oil Engines" is an instructive publication from which every power user can glean many facts about oil engine design, construction and operation—facts that point the way to better, more economical power. Request your copy through the Company Branch nearest you.

Correct Lubrication Increases Profits

MACHINERY that is perfectly lubricated with Imperial Lubricants, *wears less* and *lasts longer*. Gives maximum service, too, in every working operation. That's why superintendents and plant engineers all over the Dominion depend upon Imperial Oil Limited for their lubricating oils.

Imperial Lubricants are scientifically tested, and graded. Each grade is of unvarying high quality. From the list on the left you can select the *right* lubricant for every type of machine in your plant. Ample supplies are always conveniently available.

Correct Lubrication of all your plant units is the sure way to avoid rapid depreciation, costly shutdowns and repairs. Correct Lubrication reduces even the cost of lubricating your plant.

The regular use of Imperial Lubricants guarantees power-saving economy, increased efficiency and more profitable plant operation.

If in doubt about your present lubricating practice, Imperial Lubrication Engineers will be glad to advise you. Write to 56 Church St., Toronto.

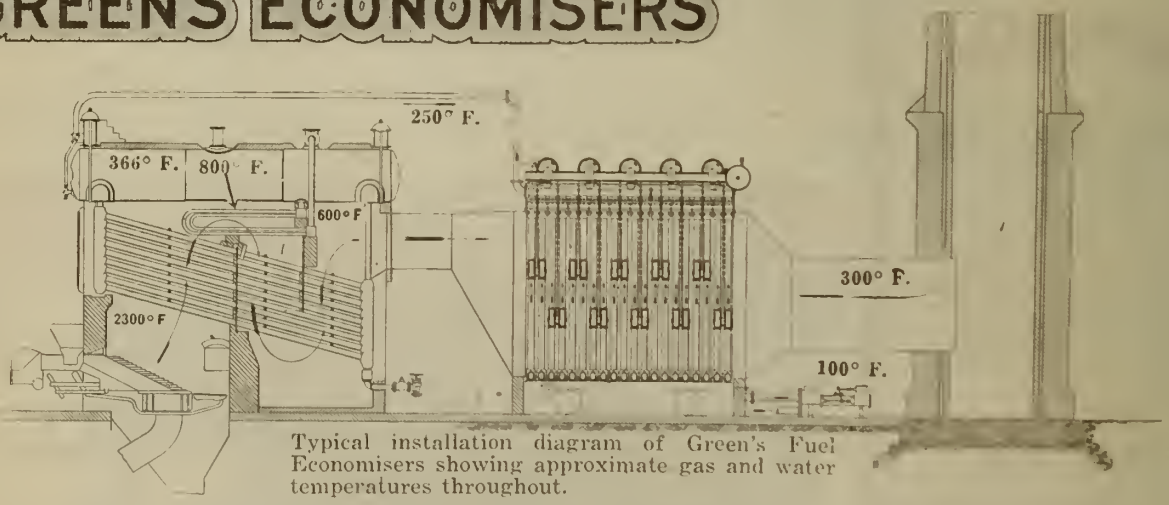
GREEN'S ECONOMISERS



Typical installation diagram of Green's Fuel Economisers showing approximate gas and water temperatures throughout.

At the recent Chemical Exposition in New York, during the fuel economy conference, one of the speakers, a noted engineer, stated that by far the greatest heat loss in the boiler room was in the sensible heat of the exit gases.

The use of extra boiler surface to cool gases below 500° F. does not pay because below 500° F. the heat absorbed per square foot of heating surface does not equal the cost of maintenance. The use of **Green's Economiser** is the **most economical method** for recovering this loss it will reduce the gas temperature to a low figure at minimum cost by transferring the heat of the gases to the feed water, under boiler pressure, thus allowing the boiler to be supplied with water at a temperature slightly lower than the steam itself

Write for our bulletin No. 151, or call for one of our engineers to inspect and make recommendations for your conditions.

DURABLA

This is the Vulcan method of cleaning boilers of the Stirling Steep Tube Type—BETWEEN THE TUBES.

Why CLEAN Boilers Burn Less Fuel

All boiler manufacturers agree on and emphasize the fact that their boilers burn fuel most efficiently and economically when the furnace fire and water in the tubes are permitted to come into contact with each other with a minimum of interference. Thus, boilers whose tubes are kept free from soot, ash and scale accumulations consume less fuel in order to maintain a given steam pressure than boilers which are regularly neglected, or only partially cleaned.

Vulcan Soot Cleaners assure thorough cleanliness so far as the soot and ash are concerned. They are responsible, in most plants where used, for saving between 4 per cent. and 8 per cent. of the fuel consumption, or for reducing the preventable losses 20 per cent. to as high as 40 per cent.

While you're thinking of it, write and ask for the interesting folder, "SPENDING $796 TO SAVE $1,017.40!"

Vulcan Soot Cleaners are manufactured for all types of water tube and return tubular boilers, superheaters and economizers. For quotations, write to either Canadian office, giving type of boiler, number of tubes wide and high, and steam pressure.

This is the famous Vulcan diagonal method of blowing as used in boilers of the staggered tube type—B&W, Goldie & McCulloch, etc.

The Safe and Certain Boiler Cleanser

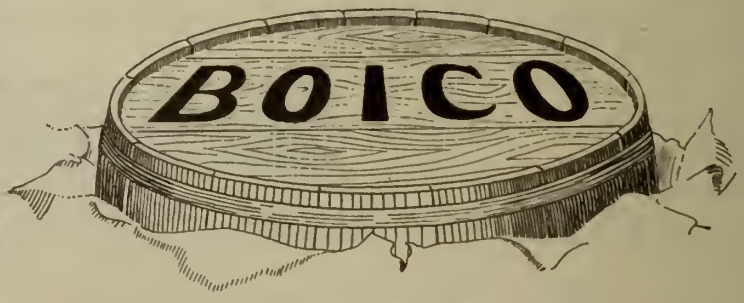
PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

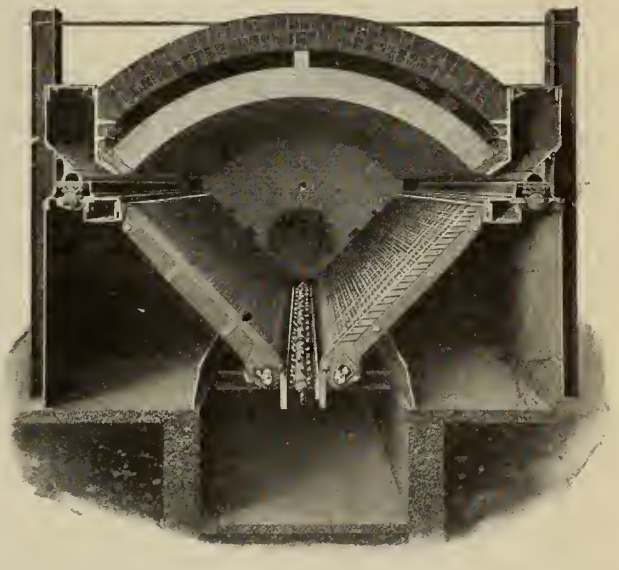
MURPHY AUTOMATIC FURNACES



For Any Boiler
50 h.p. and Up

Any boiler from 50 h.p. and up can be equipped with the MURPHY FURNACE. The *smaller plant* can, therefore, enjoy all the economical advantages of fuel and labor savings *without resorting* to forced draft.

To-day over 6,000 *boilers* are fired by MURPHY FURNACES. You will find them used in nearly every branch of the industry—from hospital to industrial and central station service.

MURPHY FURNACES "burn any fuel that has heat in it." They double the output of the plant "without one penny for draft."

Our Catalogue "HM-1" shows how MURPHY FURNACES can be installed under any type of boiler—50 h.p. and up.

For information on RILEY UNDERFEED STOKERS for large boilers, see last month's advertisement or send for RILEY STOKER Catalogue "HR-1."

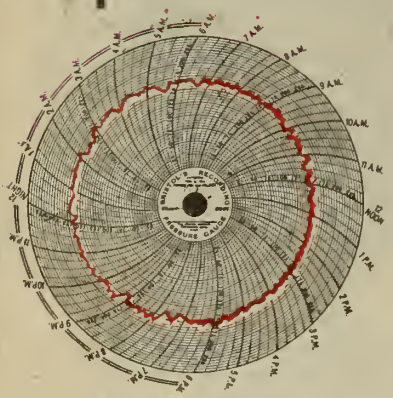
THE MASON TRADE-MARK

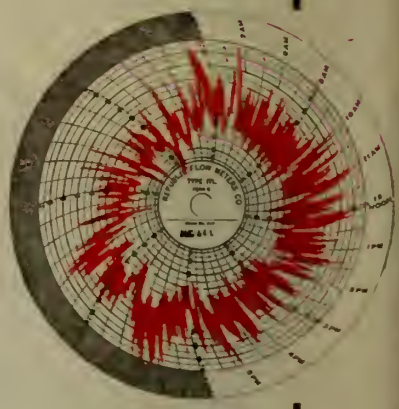
"SERVICE"

The charts on this page are from the plant of one of the largest Rubber Factories in Canada. In one of their departments it is absolutely necessary that steam be delivered at an even pressure, regardless of boiler pressure and the amount of steam used. The Mason Reducing Valve has been chosen to do this important service, as absolute reliability is essential—any variation of pressure, and therefore of temperature, meaning serious loss.



FIRST—THE BOILER PRESSURE

Fluctuating between
140 lbs. and 170 lbs.



SECOND—THE STEAM DEMAND

Ranging from 100%, or full load
to only 10% of capacity.

THEN—A GENUINE MASON REDUCING VALVE

FINALLY—THE RESULT

an absolutely even pressure day and night—never varying a fraction of a pound.

Yes, We Skinned This Tool Steel Mandril In Breaking The Jeffrey Chain Roller

"Before we selected a Pivoted Bucket Carrier for handling our coal and ashes, we made a number of thorough tests and the Jeffrey Carrier showed up fine on every one.

"The Jeffrey people told us that the Chain Rollers were so hard and tough that the bores have to be turned out on a grinder instead of in the usual way of an engine lathe. However, we split one of the rollers with a tool steel engine lathe and were convinced. The case-hardened mandril was actually skinned by the tough metal of the roller."

Emissivity of Heat From Various Surfaces

An Account of a Number of Tests Carried Out at the Engineering Experiment Station of the University of Illinois Leading to Some Interesting Results.*

By V. S. DAY

I. Introduction

IN May, 1919, it was observed in these tests that greater temperature reduction occurred in air passing through bright tin pipes covered with asbestos paper, such as are commonly used in furnace heating, than occurred in air passing through the same bright tin pipes uncovered, all other conditions in the comparative tests being the same. It was therefore evident that the actual heat loss was greater through the asbestos paper-covered pipes than through the same pipes uncovered.

This fact was reported at the annual spring meeting of the National Warm-Air Heating and Ventilating Association, Columbus, Ohio, June 11, 1919, as follows: " . . We found that we lost about 35 per cent. more heat through the pipe covered with asbestos paper than through the same tin pipe not covered. . . . This great loss amounts to approximately 5 per cent. of the coal consumed. . . . Furthermore, it costs from ten to fifteen dollars to cover the heat pipes of the average house installation with asbestos paper."*

Because of the inefficacy of many of the present warm-air furnace heat insulating methods, it is evident that a complete study of various insulating materials, coverings, and surfaces would be justified.

3. Acknowledgments.—Credit is due Professor A. C. Willard for the original idea of the scheme for testing the samples, and for the keen support which, as the active supervisor of the investigation, he gave this work.

Professor A. P. Kratz gave valuable advice and assistance in the use of the thermocouples.

4. Significant Conclusions.—The results of the tests have been given some publicity heretofore, but not in the complete form presented in this bulletin. The following significant results as applied to warm-air furnace heating are deserving of special emphasis.

(1) The use of thin sheets of asbestos paper on bright tin heat pipes results in a waste of heat. The use should be abandoned.

(2) Uncovered bright tin pipes are more efficient carriers of heated air than asbestos paper-covered bright tin pipes. See item (4).

(3) This fact is true regardless of the degree of brightness of the tin surface.

(4) No small number of applications of asbestos paper will suffice as an insulator. Several thicknesses are necessary to make a covering equal in this respect to the bare tin.

(5) The accumulation of dust and dirt on the pipes does not greatly alter the amount of the loss.

(6) The heat loss from warm-air furnace pipes covered with one layer of asbestos paper is a serious item in the cost of heating, amounting to more than 5 per cent. of the coal consumption, depending upon the number and size of the pipes used.

(7) The fact that pipes are partly protected from convection currents of air by joists and studding does not greatly affect the loss.

(8) Unless the insulation excels the uncovered bright tin in heat insulation properties it should not be used.

(9) Such materials are available and the tests have shown their merits.

II. The Testing Equipment

The report, which was made at Columbus, Ohio, gave the results of tests on the Auxiliary Testing Plant (see Fig. 6).* It was difficult to obtain entirely satisfactory data on this plant because of the variation in the velocity of the air flowing up the leader and the difficulty of correctly measuring the temperature of the air, as described later in this bulletin. It was therefore decided that a special apparatus should be devised which would eliminate possible errors in temperature measurements.

SECTIONAL ELEVATION OF STEAM DRUM PLANT FOR TESTING SURFACES FOR HEAT EMISSIVITY.

5. Description.—The apparatus here described (Figs. 1 and 2), was the one used in the tests reported in this bulletin. It consisted of low pressure steam heated drums, five in number, surrounding a central steam header from which the drums drew their supply of steam. The drums were accurately uniform in size, ten inches in diameter by twenty inches in length and were made of sheet metal of the kind to be tested. Steam was condensed in the drums by the cooling action of the air surrounding them and was discharged through water seals connected to each drum. These seals were U-tubes made of pipe, and were long enough to contain a water head of four feet. As the steam condensed the seals became filled with water; the condensate then dripped over into receivers as fast as it accumulated. The water in the seals cooled to room temperature before it dripped into the receivers so that evaporation was not influenced by the heat of the water in the receivers. Each receiver was mounted on a small weighing scales accurate to one one-hundredth pound.

A mercury manometer was used to obtain the pressure of the steam in the central header, and since the temperature of the steam for any known pressure may be taken directly from steam tables, it was possible to determine the temperature of the medium within the drum with great accuracy. A pressure regulator in the steam supply line held the pressure constant within a small fraction of a pound, about 0.2 pound being the variation during a test; as the temperature change for the pressure variation was negligible, the temperatures were uniform and accurate within one degree.

No thermometers were required for determining the steam temperature, but one was used in each drum at the point of outlet of the condensate to detect the presence of air in the drums. The readings of these thermometers decreased upon the formation of air pockets in the lower part of the drums or in the connected piping. Air could be blown out of small petcocks located near the thermometers in the piping. No effects on the co-efficients were noticeable when steam was allowed to escape for short periods from these petcocks, which could therefore be opened during a test to discharge any small accumulation of air.

A SAMPLE DATA SHEET FOR A TYPICAL TEST.

The drums were shielded from radiation from each other by blackened compo-board partitions. These partitions did not in any way interfere with the flow of natural air currents. The temperature of the air was measured by thermometers suspended at the elevation of the drums at convenient positions nearby. The thermometers were not affected by radiation from the drums.

Thus the actual measurements involved were simple and were not liable to serious error. These measurements consisted of the weighing of the steam condensed, the reading of the pressure of the steam, and the reading of the room air temperature.

III. The Tests

6. Operation.—The tests reported herein, forty in number, with four drums under steam in each test, were carried out at night when the doors and windows of the large laboratory were closed. No air currents were noticeable near the apparatus. A period of ten hours was chosen for the duration of a test as that time was sufficient to permit accumulations of condensate great enough to render negligible the slight error in weighing. These quantities of water varied from 5 to 20 pounds depending upon the surface material of the test drums. The steam pressure was constant on any given test within 0.2 of an inch head of mercury. In all the tests there was only one case in which the thermometers indicated the presence of air in the drums at the end of ten hours operation. The greatest variation of temperature of the surrounding atmosphere during any night was four degrees Fahrenheit. A recording thermometer was used to show the uniformity of the laboratory temperature.

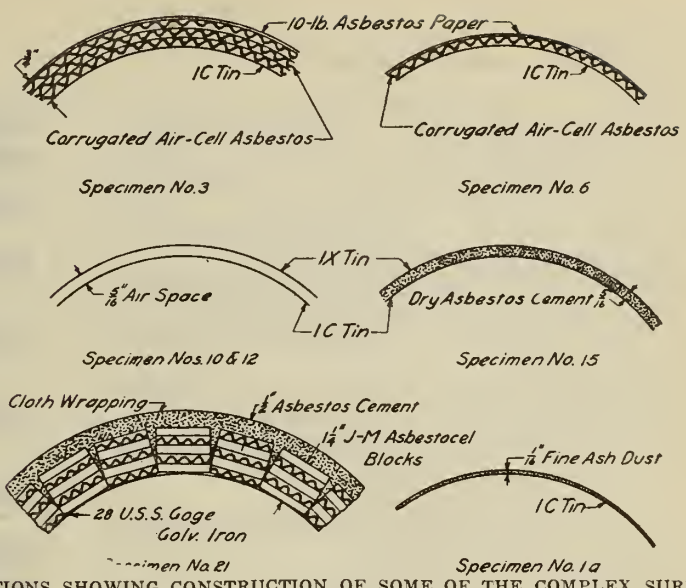
The drums were tested in different positions around the steam header in order to compensate for any irregularity in the flow of steam to the drums or in the currents of air about the drums. As no irregularities were noticeable in the values of the co-efficients of emissivity for the various positions, the practice

was abandoned after the first four drums were tested in the interchanged positions.

One drum, of bright tin not insulated, was in operation in all tests. Its performance served as an indication of any lack of uniformity in the conditions existing throughout the tests.

In order to make correction for the loss of water by evaporation from the receivers, a receiver of water was balanced on a scales and the loss in ten hours actually determined by weighing. After several trials in which the loss ranged from 0.10 to 0.12 pound it was decided to use the value 0.11 pound. This amount was applied as a correction to all the weights of water. Every test was repeated until the results obtained were found to agree within very small limits. In no case are the data reported, the result of less than two tests, and in most cases four were run. Two tests were considered sufficient if the results agreed within one per cent. of their mean value.

7. Specimens Tested.—A complete list of the drums tested is given in Figs. 5 and 5a. In the list will be found a description of the insulation or the surface material, the actual area of the drum exposed to the steam, and an abstract number assigned to the drum (which will be useful in connecting the description with the results reported later in this paper). Fig. 4 shows sections through some of the insulations which were of complex construction.



SECTIONS SHOWING CONSTRUCTION OF SOME OF THE COMPLEX SURFACE COVERINGS.

IV. The Calculations

In calculating the co-efficients of emissivity for the various surfaces it was assumed that heat of the vapor was entirely given up, upon condensation, to the air through the walls of the containers and the connected piping. Tests on the low pressure steam-line supplying the drums show a steam quality of over 99 per cent. The expression for the co-efficient is, therefore, calculated as follows:

$$K_1 = \frac{rW}{A\,(t_s - t_a)} \quad . \quad . \quad . \quad (1)$$

in which, K_1 = B. t. u. per sq. ft. per hr. per 1 degree F.

r = latent heat of one lb. of the steam.

W = weight of condensate per hour.

t_s = temperature of the steam.

t_a = temperature of the surrounding air.

A = area of the drum exposed to the steam.

Correction must be made for the loss of heat through the half-inch pipe of which the water seal was made. This loss is not accounted for in the calculation for K_1 above. Three lineal feet of the half-inch pipe were exposed to the steam. The correction is made by using a co-efficient of emissivity for this pipe of 2.50 B. t. u. per sq. ft. per hr. per 1 degree F. and the exposed area of 0.375 sq. ft., or, 2.50x0.375 = approximately 100 B.t.u. per hour per 1 degree F. to be subtracted from the heat loss, or,

$$AK_1\,(t_s - t_a) - 1.00\,(t_s - t_a) = AK\,(t_s - t_a)$$

$$\text{and } K \text{ corrected} = \frac{AK_1 - 1.00}{A} \quad . \quad (2)$$

This correction was verified by tests made on the drums with the water seals heavily insulated with hair felt. The values of K so determined agree closely with the values obtained by applying the correction.

Fig. 3 is a copy of a test data sheet and shows all readings and calculations for one test.

V. Results of the Tests

8. Discussion.—The significance of the tests will be best understood by a study of the information presented in the diagrammatic chart, Figs. 5 and 5a. The heavy black bars afford a graphic comparison of the heat emitting value of the various surfaces. Reference must be made to the descriptive list of drums in order to connect the data with particular test specimens. The relative efficiencies of the various surfaces as heat insulators are given in the next to the last column of the chart. The co-efficient for bright IC tin was used as the basis for this comparison.

The first result of importance is the convincing evidence which the tests present as an argument against the use of thin layers of asbestos paper covering on bright tin pipes. The heat loss was 39 per cent. greater with one thickness of the paper than without. Such a loss is of no small degree of importance as calculations will show that it results in a waste of 5 per cent. or more of the coal consumed in the average house furnace.

The fact that the heat loss from the warm-air pipes of a furnace system is of some consequence is not appreciated generally. A considerable part of the heat of the air flowing through the pipes of the average installation is dissipated from the pipe surface to the surrounding air and nearby objects. The insert in Fig. 6 sets forth the results of tests made to determine the amount of this loss. The tests were carried out on a single leader pipe furnace,* see Fig. 6, in which the quantity of air handled and the heat content of the same above the entering temperature could be readily ascertained. The heat loss was determined by calculation from the drop in temperature of the air in its passage through the pipe. The temperature and velocities indicated in the curves are fair representative values.

The significance of these preliminary tests is to bring out the fact that the heat loss from warm-air furnace pipes is a serious item. From the curves it can be seen that in the case of the asbestos paper-covered pipes the loss amounts to about 23 per cent. of the heat of the air at the bonnet, above inlet air temperature. If the pipe is of bright tin and not covered this loss is reduced to about 17 per cent. of the heat available. In either case the loss is great; and with the further consideration that a warm-air furnace under average conditions of installation is, at best, only about 60 per cent. efficient, it will be understood that the actual waste of coal ascribable to poor heat pipe insulation is enough to warrant attention.

The attempt was made in the steam drum tests to determine the effect upon the heat loss of having the drum partly enclosed so that free circulation of the air about the drum would be prevented. The experiment simulated the effect of running leader pipes between joists. The results of these tests as shown in No. 14 and No. 14a indicated a slight decrease in the value of K for the enclosed drum.

The argument has been advanced that if bright tin pipes were used without

DIAGRAMMATIC TABLE OF THE RESULTS OF 160 TESTS ON STEAM DRUMS

covering, they would soon become fouled with dirt and dust and so rendered less efficient heat carriers than asbestos paper covered pipes. The fallacy of this argument is revealed by tests No. 1a and No. 16a. In these tests fine ash dust was sifted on the test drums, one of bare bright tin and the other asbestos paper covered. The dust was more than one-sixteenth inch deep on top of the drums. The results as shown in tests No. 1a and No. 16a of the chart indicate that the bare tin suffered a loss of 11 per cent. in efficiency whereas the asbestos paper surface improved 2.4 per cent. There still remained, however, a difference of 25 per cent. in favor of the bare tin pipe.

In order to demonstrate further the inefficacy of thin layers of asbestos paper as a heat insulator, tests were run in which the number of thicknesses of paper was increased until the heat loss became less than the loss through a bare, bright tin specimen. The curve (Fig. 7) gives the results of these tests. Eight thicknesses of the twelve-pound paper were applied before the desired result was obtained. In these tests the moistened paper was wrapped tightly and shrunk on the drums so that only a small quantity of air was entrapped between the successive layers of paper. The total thickness of paper was two-tenths of an inch. The impractical features of such a method of insulating are, of course, evident. The use of thin layers of asbestos paper on bright tin pipes must be abandoned if the best results are to be obtained in furnace heating.

Other materials of better heat insulating value than the bare tin were tested. Numbers 3, 6, 10, 12, 15, 18, and 21, all show values which indicate that a large saving would be effected by their use. Some of them are expensive and not easy of application, but good selections may be made. The air-cell combinations Nos. 3 and 6 are excellent insulators, are easy to fit to basement leaders, are not expensive, and the latter, in particular, is not bulky.

The double wall tin pipes Nos. 10 and 12 are very efficient insulators and are easy to construct and to install. Other tests are in progress which are expected to establish still further the merits of this type.

The tests on galvanized iron specimens brought out the fact that the heat loss through this material is not greater than through bright tin of the same gauge. This low heat radiating property is an argument in favor of the galvanized iron leader pipe. Nos. 18 and 21 are good insulations for the exterior of furnace casings, the heat loss through the latter being almost negligible. No. 21 is very easily applied.

The tests on drum No. 11 were made to determine the effect of transparent applications on the tin surface. Bakelite lacquer was used. The result was a slight increase in the heat loss. It was thought that the use of the lacquer would be justified in practice by its rust preventing qualities, but specimens exposed to steam laden air for long periods show no advantage for the protective coating.

Tests Nos. 20 and 23 were made for the purpose of ascertaining the effect of color upon the heat radiating value of a surface. Applications of white calcimine were made on a drum which was tested; then a coat of dull black calcimine was added and the drum re-tested; a final coating of white calcimine was applied and the drum again tested. The alternate tests with white calcimine checked very closely proving that the additional thickness of the calcimine was not sufficient to have any bearing on the results. Beyond demonstrating the superior radiating value of a dark surface, the tests have little significance.

Specimens Nos. 4 and 5 demonstrated the uneconomical effect due to increased heat loss of any kind of oil paint applications on heat pipes. A comparison of Nos. 1 and 4 will show the enormous increase in heat loss caused by painting bright tin heat pipes, and a comparison of Nos. 2 and 5 will show the similar

Drum Number	Description of Surface	Area Exposed to Steam sq. ft.
14a	Same as No. 14 with housing removed	5.51

CONTINUATION OF DIAGRAMMATIC TESTS.

wasteful effect of painting over the asbestos paper covering. However, the use of paint on asbestos paper has in its favor the moisture-proofing effect of the paint.

Other information of value may be found in the data given in the table. To use these data for the determination of the approximate heat loss from a heat pipe, it is only necessary to multiply the value of K for the surface by the surface area of the pipe exposed and further multiply by the difference in temperature between the air inside and outside the pipe, or,

B. t. u. loss per hour = K x Area in sq. ft. x $(t_i - t_a)$

On account of the difficulty of correctly measuring the temperature of the air near the inner surface of the pipe, the method of determining the loss from a pipe as here given is only approximate.

VI. Corroborative Tests

9. The Auxiliary Air Plant.—In order to show the connection between the work done on the steam drums already described and conditions obtaining in a warm-air system, the following account of experiments conducted on the Auxiliary Furnace Plant which is shown in Fig. 6 of this bulletin is given. In these experiments the weight of air flowing up the pipe was determined by the use of the steam-air meter which supplied the heat. Half way along the ten-foot length of the ten-inch leader pipe was located a traversing device (Fig. 8) which made it possible to get temperatures at any point across the pipe diameter by intervals of one-hundredth of an inch. A thermocouple was used in the traverse and its readings were accurate within one degree Fahrenheit. A second couple was tinned to the surface of the pipe and by rotation of the pipe (a short section could be turned) temperatures at any point on the surface in the plane of rotation of the couple could be determined.

10. Temperature Measurement.—The couples used in this work were made of copper and constantan wires of No. 22 gauge. The junctions were silver soldered. Fig. 8 shows the wiring arrangement and the instruments used for two couples. As many couples may be used as there are contact points on the selector switch. Four were used on the leader pipe for the tests here described. The couples were calibrated individually in a hot oil bath over a range of 200 degrees, and calibration curves were carefully drawn. It is possible to repeat readings of the pyrovolter within 0.01 millivolt which by calibration is 0.4 degree Fahrenheit. This insures an accuracy of reading of one-half degree. As the couples were soldered to the surface of the pipe in some parts of the work, it was thought advisable to repeat the calibration after the couples were removed from the pipe. The constancy of the couples was found to be unaltered by the soldering to the pipe.

The use of thermometers for accurate temperature measurements in an air stream is not satisfactory. Thermometer readings will not be in agreement with thermocouple readings though both are suspended in close proximity in the same stream of moving air. For this reason thermocouples were used throughout these tests.

In Fig. 9 are given temperature traverse curves showing the variation in temperature across the ten-inch pipe. Curves are shown for both the asbestos paper-covered pipe and the bare pipe, all other conditions of the tests being identical. The curves demonstrate the heat-radiating value of the asbestos paper. Note that not only the air temperature but the surface metal temperature beneath the paper is lower in the case of the covered pipe, this fact indicating that the tin is conducting the heat to the asbestos covering, which in turn radiates it more rapidly than does uncovered tin. Very exact means were

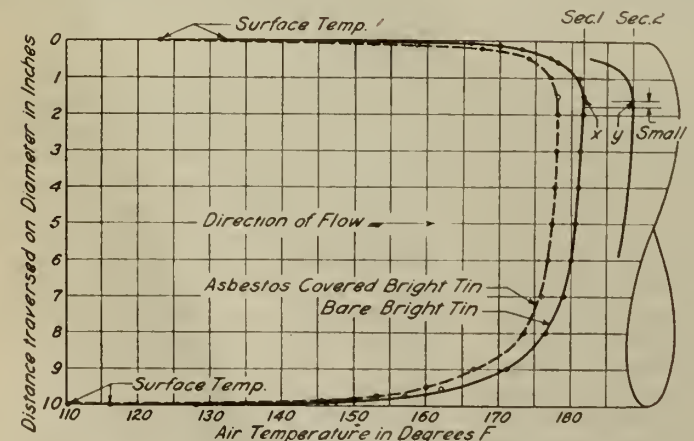
taken to determine the temperature of the film of air in contact with the inner surface of the pipe. The traversing couple, made of wire 0.025 inch in diameter, was filed flat at the junction so that it was less than 0.02 inch thick. Measurements of the temperature were made with this thin couple at a distance from the pipe surface just great enough to cause a break in an electric circuit through the couple and the pipe, the break being indicated by a small voltmeter in the circuit. The distance was less than 0.01 inch from the pipe surface. The temperatures were found to differ from the metal temperature 15 to 30 degrees, the greater difference existing in the case of asbestos paper-covered pipe. (See the sample data sheet Fig. 10 for data on these measurements.)

The temperature change of the air flowing in the pipe was determined by the use of couples suspended in the air



TEMPERATURE TRAVERSE CURVES OF TEN-INCH LEADER PIPE.

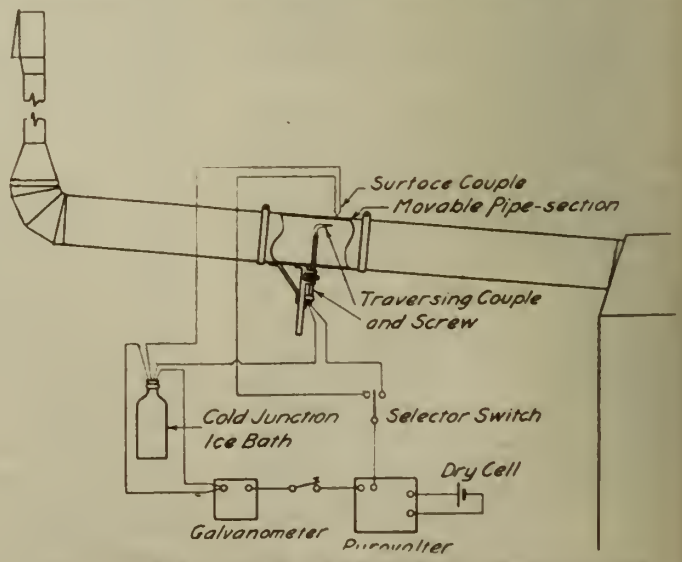


DIAGRAM OF THERMOCOUPLE CONNECTIONS TO THE AUXILIARY TESTING PLANT.

stream three inches below the top of the pipe. These couples correctly register the temperature drop of the mass of air between any two sections for the reason that the traverse curves are similar in shape at all sections along the pipe, and the error in reading the temperature due to a difference in the traverse curve is very slight. This fact is illustrated in Fig. 9 at Sec. 1 and Sec. 2. It will be seen that a great difference in the shape of the traverse curve would be necessary to cause serious error in determining the temperature drop along the path of flow of the air.

In measuring the temperature of the pipe surface it was found that whereas the air in the pipe dropped in temperature, the pipe itself showed a measurable increase in temperature away from the furnace. This slight increase occurred when the pipe was covered as well as when bare. As this increase amounted to only about 3 degrees and was proportional to the length of pipe, it was considered permissible to use the temperature half way up the leader as the mean metal temperature.

11. Calculation.—The co-efficient of emissivity for the pipe surface may be calculated since the heat loss through the surface of the pipe between any two sections is equal to the decrease in the heat content of the air in its passage through the length of pipe between the two sections, or,

$0.24\ W\ (t_1-t_2) = A\ (t_5-t_6)\ K_1 \ldots (3)$

in which W is the weight of air flowing.

t_1-t_2 = the temperature drop of the air in the given length of pipe.

A = the area of the pipe exposed in the given length of pipe.

t_5-t_6 = the drop in temperature between the metal of the pipe and the air.

K_1 = the co-efficient of emissivity not corrected.

Solution of the equation will furnish a value for K_2, which will not, however, check or agree with the value determined in the steam drum tests of the same material. The variation may be easily explained since it is a well-established law that the co-efficient of heat emissivity of a hot body varies with the temperature difference between the heating and the cooling medium. (See tests of radiators by J. R. Allen which demonstrate this fact).

In the case of the heat pipe the temperature traverse showed a low air temperature near the inner surface of the pipe and also a correspondingly low temperature of the metal of the pipe. The result is a comparatively low value of t_5-t_6 and according to the law, a low co-efficient is to be expected.

The following case will illustrate: the pipe was covered with 12-pound asbestos paper. The surface couple showed that the temperature of the tin beneath the paper was actually lower than the temperature in the case of a bare pipe.

TEN SAFETY COMMANDMENTS

1. Thou shalt have no thoughts other than thy work.
2. Thou shalt take no unnecessary risks nor try to show off nor play practical jokes, for by thy carelessness thou mayest do injury which will have effect upon the third or fourth generation.
3. Thou shalt not swear nor lose thy temper, when things do not come just right.
4. Thou shalt not clean machinery while it is in motion.
5. Remember that thou art not the only one on the job and that other lives are just as important as thine own.
6. Honor thy job as thyself, that thy days may be long in employment.
7. Thou shalt not watch thy neighbor's work, but attend to thine own.
8. Thou shalt not let the sleeves of thy shirt hang loose nor the flaps of thy coat unbuttoned, as they may get caught in the machinery.
9. Thou shalt not throw matches or greasy waste on the floor nor scatter oil around bearings, as a dirty worker is also a clumsy worker and a clumsy worker is a menace to his fellow workers.
10. Thou shalt not interfere with the switches, nor the cables, nor the engines, nor anything else that thou art told is dangerous.

An ounce of prevention is worth a pound of cure.

Every man's task is his life preserver.

To live long it is necessary to live carefully.

Doing nothing is an apprenticeship to doing wrong.

$W = 479$

$t_1-t_2 = 17$

$t_5-t_6 = 44$

$A = 26.40$

$$K_2 = \frac{479 \times 0.24 \times 17}{44 \times 26.40} = 1.77 \text{ B. t. u.}$$

per sq. ft. per hr. per 1 degree F.

Assuming that the correction of 0.1 per cent. per degree F. below the standard range of 150 degrees which is used in making corrections with direct radiators applies to this surface,* the value of K becomes:

$K_6 = K - 0.002\ K\ [150 - (t_5-t_6)]$

$1.77 = K\ [1 - 0.002\ (150 - 44)]$

$K = 2.24$ B. t. u. per sq. ft. per hr. per 1 degree F.

This result is in close agreement with the value of K = 2.08 as determined in the steam drum tests and reported above.

12. Conclusion.—Enough tests have been made on this apparatus to entirely corroborate the results obtained on the steam drums, and additional tests are in progress in which more exacting methods are employed.†

*"Mechanical Equipment of Buildings," by Harding and Willard, vol. 1, p. 78.

†For further information regarding the tests involving the use of thermocouples on this plant, see University of Illinois Engineering Experiment Station Bulletin No. 112, "A Report of Progress in Warm-Air Furnace Research," by Prof. A. C. Willard. An abstract of this bulletin was presented at the Annual Meeting of the American Society of Heating and Ventilating Engineers, at New York, January 28, 1920.

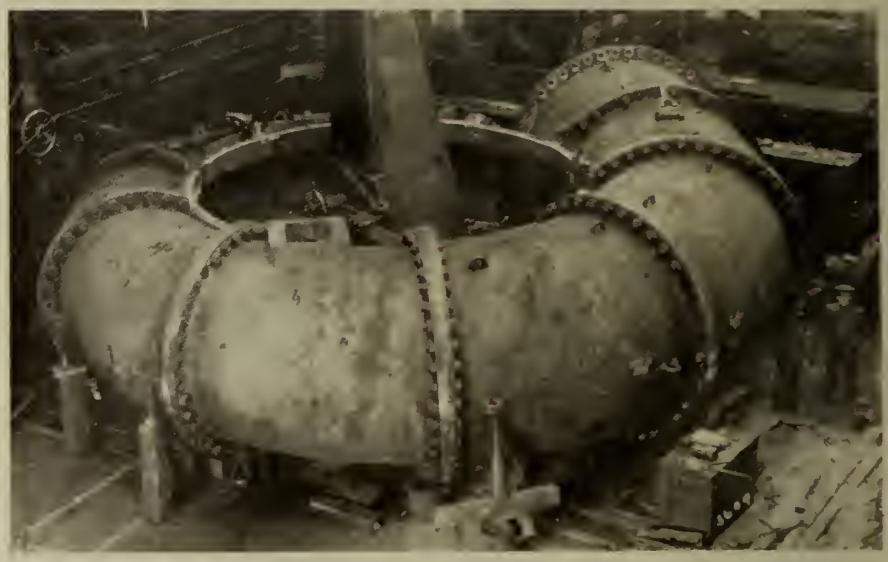
By means of a method of chemical analysis, in which the electric arc is utilised, Mr. W. R. Mott, an American research chemist, claims to identify readily about sixty-five elements, picking them out from their ores, compounds with oxygens, or alloys. According to the Chemical Trades Journal, the apparatus required is simpler than that for spectroscopic analysis, and includes a carbon arc lamp so enclosed as to project upon a screen an image magnified 20 diameters. A half-gram sample of the material to be tested is placed in a cup-like cavity, two-fifths of an inch wide and deep, hollowed out of the positive lower carbon of the pair. The elements are recognized by various phenomena, including the nature and colors of the material deposited on the carbon pole from distillation, the smoke, sparks and flame-tip color shown, and the odor of the fumes emitted, with many other peculiar characteristics. The smoke emitted from the hot upper carbon when the arc is broken appears only when molybdenum is present, being a delicate test for that element. The present of calcium is shown by its peculiar red color, and characteristic odors reveal iodine, arsenic, and tungsten. Many elements difficult to determine in other ways are said to be clearly identified by this new system.

D. M. McLean, formerly chief engineer of the Dover Boiler Works, Dover, N. J., general sales manager of the L. & I. J. White Company, Buffalo, N.Y., etc., and for the past four years manager of the publicity department of the Canadian Ingersoll-Rand Company, Sherbrooke, Quebec, recently left the latter company to assume control of C. & C. Limited, Rock Island, Quebec, manufacturers of fancy biscuits and candies. Mr. McLean's son, F. A. McLean, A.M. C.M.I., and formerly with the Crocker-Wheeler Company, Lackawanna Steel Company, McKiernan Terry Core Drill Company, etc., and latterly general assistant publicity department Canadian Ingersoll-Rand Company, has been appointed as his successor.

The Hydraulic Turbines for Niagara Falls

Each of These Machines Will Develop 61,000 B.H.P. at 187½ R. P. M.—They Will Be Coupled to 45,000 K.V.A. Vertical Generators—The Turbine Casing Weighs 110 Tons

IT is quite natural that the most powerful hydraulic turbines should be installed to generate power at Niagara Falls, the sight of which impresses the most casual observer with their immense power possibilities. The Ontario power plant at the foot of the Canadian Falls is now controlled by the Hydro-Electric Power Commission of Ontario and is the largest plant on their system. This plant has sixteen hydro-electric units with a total capacity of 240,000 H.P. The head available at this plant is only 180 feet. By carrying the same amount of water on the Welland River four and one-half miles, thence through a nine mile canal skirting around the corporate limits of Niagara Falls, Ontario, to a point near Queenston, the Hydro-Electric Power Commission will increase the net effective head on the turbines to 305 feet and obtain 70 per cent. more power with the same quantity of water. This development will provide the most economical and efficient use of the available water at Niagara. Water will be taken at a point two miles above the Falls at practically the same elevation as Lake Erie and will be discharged into the river one-half mile from Queenston at about the level of Lake Ontario. The canal will be 48 feet wide by 35 feet deep in rock cut and 70 feet wide by 35 feet deep in earth cut.



MACHINING OF S.C. SPIRAL CASING FOR 52,500 H.P. SINGLE VERTICAL TURBINE.

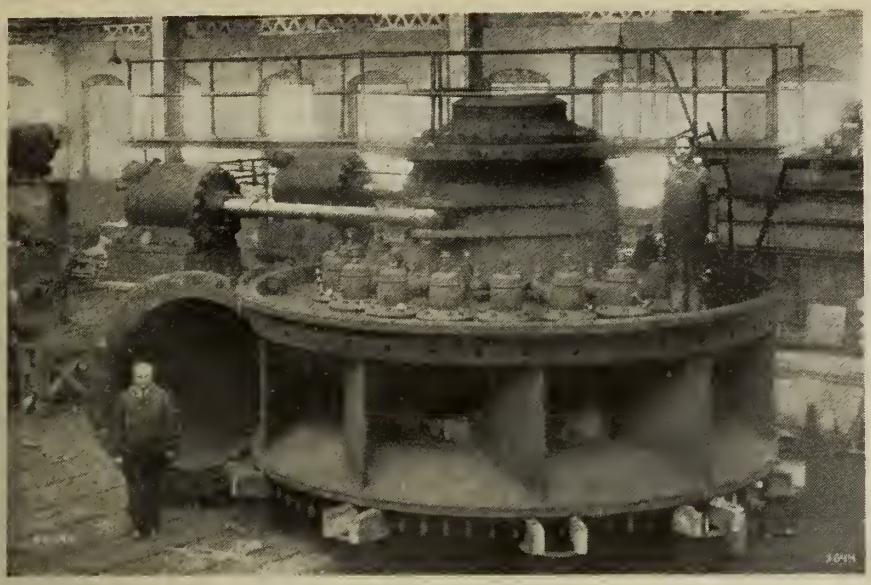
The Power House

The power house is located at the foot of the cliff at the end of the canal which terminates with a forebay in front of the intake gate house. The water is conducted to each turbine through a 14-foot diameter plate steel penstock about 450 feet long. As the system which this plant supplies is one of the largest on the continent, the capacity of the units was made as great as present practice in hydro-electric units would warrant in order to minimize the number of units. Each turbine at full gate will develop 61,000 B.H.P. at 187.5 R.P.M., and it is intended to operate each machine at from 47,000 H.P. to 55,000 H.P. through which range the highest efficiencies occur. The weight of the turbine equipment is 625,000 pounds exclusive of the governor apparatus. The turbines will be coupled to 45,000 K.V.A. vertical generators being built by the Canadian-Westinghouse Company, Ltd., at Hamilton, Ontario.

The first two turbines for this installation have been designed and are being built by the Wellman-Seaver-Morgan Company of Cleveland, Ohio, who are especially well equipped to make the large steel castings and machine the large sections necessary in units of this type.

The turbines are of the single runner vertical type with downward discharge into a single draft tube. The water is distributed around the circumference of the turbine through a cast steel spiral or scroll casing having approximately circular cross sections. It is then guided to the runner and the velocity increased through the cast steel speed ring and gates. The stationary vanes of the speed ring form the tie across the throat opening of the spiral casing and also to withstand the hydrostatic pressure inside the casing and also to transmit part of the load of the concrete and generator above. The inlet diameter of the spiral casing is 10 feet and the distance across the casing at the widest part is about 38 feet. From the center to the extreme edge of the inlet flange is 22 feet. The casing was made in nine sections. When bolted together with the speed ring the casing was subjected to a very satisfactory shop test of 260 pounds per square inch water pressure which is over double the normal working pressure. Measurements taken during the test showed that all parts safely withstood this test with-

SECTION OF SPIRAL CASING ON BORING MILL.



ASSEMBLY OF TURBINE SIDE VIEW.

out any excessive strains being set up in the castings or bolting. Figure 1 shows the casing set up in the shop for the pressure test.

In order to secure castings to safely withstand this test pressure the various sections were cast on end so that all impurities would float out into the risers, leaving the metal perfectly sound. The moulds were made in green sand and with a green sand core. In making up the mold the core was rammed up inside the skeleton pattern which was then taken off and the core smoothed up. The pattern was again placed around the core, the flasks put in place, rammed up, then removed and smoothed up on the inside. The pattern was finally removed and both the core and flask dried out to insure a hard surface for the mold. The flasks were arranged with a parting midway of the height of the mold to facilitate removal and replacing them. The castings obtained were very uniform in thickness and exceptionally sound in every respect. The tests of the metal ran from 70,000 to 85,000 pounds per square inch tensile strength and the elastic limit from 40,000 to 52,000 pounds per square inch. The largest section of the casing weighed 37,000 pounds—the whole casing weighing slightly over 110 tons.

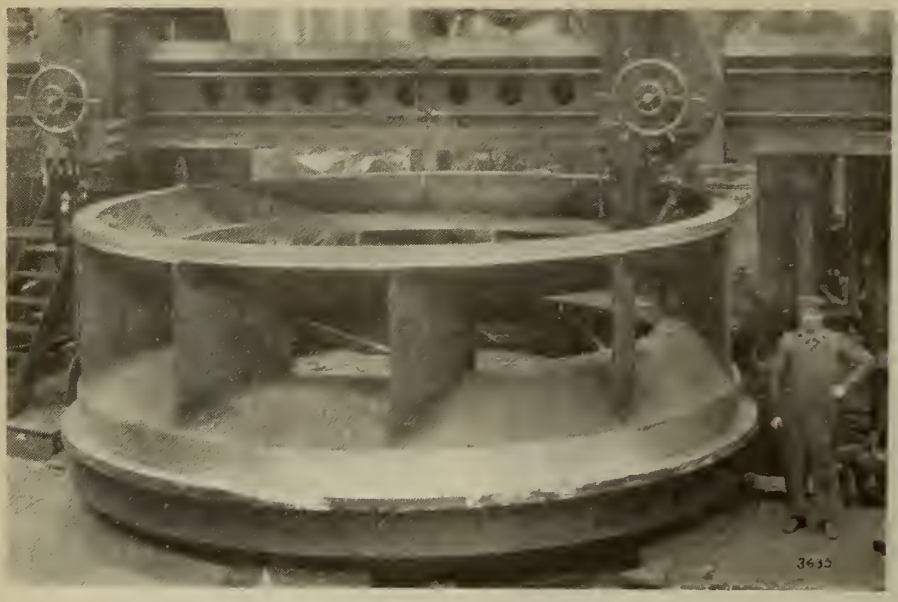
To facilitate the machining of the individual sections of the casing at the radial joints, six of the sections were designed to subtend an angle of 36 degrees. This feature permitted each of these sections to be set up on an inclined fixture mounted on a large boring mill so that the upper surface could be faced off horizontally, the casting then turned over and the other flange faced. After facing off the ends of the sections were drilled, bolted together and set on supports around the table of a large boring mill. The vertical housings of the mill were moved back and the tool post bolted to the table of the mill in order to machine the inner faces to which the speed ring is bolted.

One of the runners for these turbines is shown in Figure 2. It is made of steel cast in one piece and weighs 33,000 pounds. Extreme care is taken in setting the cores for this casting as the water passages and vanes must be uniform, smooth and true to design in order to secure high efficiency and to preclude corrosion. These runners when completed are accurately balanced and great care is taken in truing up the runner and shaft to insure perfect operation. When running at 500 R.P.M. no vibration whatever could be measured.

The turbine is so designed that the runner may be disconnected from the flange coupling on the end of the main shaft and removed from below the turbine casing without dismantling the generator or disturbing the alignment of the unit.

The main shaft at the coupling end is 30 inches diameter and through the bearing it is 31 inches diameter. It is hollow bored to 8 inch diameter throughout its length of 22 feet 3 inches, in order to pass a cable through for handling the runner and removable draft tube when dismantling by use of the crane in the generator room. On account of the flange being 53 inches diameter at the generator coupling and 51 inches diameter at the turbine coupling it was necessary for the Midvale Steel and Ordnance Company to forge these shafts from 63 inch octagon ingots weighing 122,000 pounds. The finished shafts weigh 54,200 pounds.

125" DIAMETER STEEL RUNNER.



CAST STEEL SPEED RING FOR 52,500 H.P. TURBINE.

The gates are made of steel with the stems cast integral with them and are machined all over, which insures a proper guide for the water with a minimum of friction. The cast steel levers on the ends of the gate stems are connected to the cast steel operating ring by cast iron links. These links are designed to break before the elastic limit of any of the other parts of the gate mechanism is reached.

Two 24 inch x 15 inch governor cylinders, bronze lined to prevent rusting, are used to operate the gates of each machine. They are connected to the operating ring by 6¼ inch diameter piston rods. The operating fluid for the governor pressure system will be a mixture of water and a small amount of oil. In case of emergency the governor system can be connected through strainers to penstock pressure.

Every hydraulic feature has been carefully studied to develop the highest attainable efficiency. In the mechanical design the aim has been to obtain strength, ruggedness and simplicity throughout to insure satisfactory and continuous operation. Completely erecting the turbine in the shop will preclude any unnecessary fitting or machine work in the field.

William Beardmore and Company, of Scotland, have opened a Canadian office at 385 Beaver Hall Hill, Montreal. This firm carries on an extensive business in many lines of engineering activity, manufacturing steel shaftings and forgings of all sizes types and axles, small tools, jigs and fixtures, locomotives of every description, lapwelded furnaces and flanging work of all kinds. They are builders of steam, turbo, Beardmore-Tosi, Diesel and Beardmore crude oil engines, centrifugal and semi-rotary wing pumps. They are also naval constructors, having built H. M. S. Raleigh and other war vessels.

31 AND 30 INCH DIAMETER SHAFT.

OBITUARY

Mr. F. C. Harding, secretary of the Toronto No. 1 Lodge, C.A.S.E., and chief engineer of the Christie Street Hospital, died as a result of asphyxiation by carbonic acid gas. Mr. Harding was running his automobile engine in an enclosed garage and the gas evidently accumulated without notice by him, until it mounted high enough to be drawn into his lungs. The sympathy of all members of the C.A.S.E. and of Power House is extended to Mrs. Harding.

The death occurred on January 7 of Edward G. Little, engineer of the local Hydro power plant, at Erindale, Ont.

Charles W. McGuire, manager of the Imperial Oil Co., London, Ont., died on January 9th at his home, 799 Hellmuth avenue, following several weeks' illness from heart trouble. Mr. McGuire was one of the most prominent Masons in Western Canada.

Mr. J. M. Fairbairn, chief engineer of the Canadian Pacific Railway, is to be installed as president of the Engineering Institute of Canada at the annual meeting of the organization, which will be held in Toronto during the first three days of February. Mr. Fairbairn is a graduate of the School of Practical Science, Toronto University, and joined the C. P. R. in 1899 as assistant engineer in the construction department.

The Hydro Commissioner for Hamilton, Mr. Guy Long, announced after the first meeting of the year that there was power available for either domestic or commercial purposes, the commission having 3,500 H. P. which they wished to dispose of. Mr. Long did not think that there would be any power shortage this year.

At a meeting of the Scarboro' Township Council, the proposed waterworks were up for discussion. Tenders were received for $130,000 waterworks debentures. The township clerk and the public utilities commissioners have had a conference with the York County Engineer, Mr. A. E. James, with reference to the project, and preliminaries have been commenced. It is hoped to go ahead with the job.

The City of Calgary is using lignite slack for the production of power in their turbo electric station. The slack only costs 25 cents at the mines, and about $2.30 a ton on the plant. This compares with a cost of $7.67 per ton for bituminous slack. An average of .368 cents per kilowatt hour was obtained. The average consumption was 4.46 per kilowatt hour, the lowest being 3.47 pounds and the highest 5.77 pounds. A matter of pride to the electric power force of the city is the fact that there has been no shut down of power in the centre of the city for three years. This is a creditable record.

Another Fatal Boiler Explosion

ONE of the most important duties of a fireman or engineer in a boiler plant is to keep the water in the boiler at the proper level; and it is particularly important to see that there is sufficient water in the boiler before starting up the fire after it has been banked for the night or over a holiday. Failure to take this precaution was probably the cause of the explosion which is described and illustrated in this article, and as a result of which two men were killed and five others were injured. The explosion also caused damage to the surrounding property to an amount estimated at from $7,000 to $10,000.

The exploded boiler was of the horizontal return-tubular type, and was built in 1904. It was 72 inches in diameter and 16 feet long, and contained 80 tubes each 4 inches in diameter. The longitudinal seams were of the lap-joint type, and a working steam-pressure of 100 pounds per square inch was allowed on the boiler.

THE BOILER ROOM AFTER THE EXPLOSION.

We are informed that the man in charge of the boiler arrived at the plant on the day of the explosion at about 5.30 a.m.; and soon after this, aided by some other employees, he proceeded to start up the fire which had been banked over night. When he had worked for about half an hour without being able to raise more than a few pounds pressure (as shown by the steam gauge), the engineer, apparently for the first time, looked at the water gauge-glass and discovered that no water was visible. He then attempted to start the feed-pump, but found difficulty in doing so on account of the low steam-pressure. He therefore returned to the front of the boiler, intending to haul the fire. Just at this moment one of the factory employees, who was in the boiler-room, called attention to the fact that the steam gauge registered a pressure of 80 pounds, and almost immediately thereafter the boiler exploded. The setting was demolished and the walls of the room were badly damaged. The rear end of the boiler was moved about four feet to the right, and the front end about six feet in the same direction.

Seven men were in the boiler-room when the explosion occurred. Two of them died from the injuries received, another was seriously hurt, and the remaining four men escaped with only slight injuries.

The master mechanic of the plant arrived on the scene about twenty minutes after the explosion, and he is said to have stated that at that time the boiler and the tubes were still red-hot.

A subsequent examination of the wrecked boiler showed evidence of overheating in all the tubes, and in that portion of the shell exposed to the fire. The soot was all burned off these parts, and the metal had the appearance characteristic of overheating. A rupture extended the entire length of the middle course, and the edges of the break were drawn down very thin. A second opening about four inches long was found near the large rupture, and for several feet from each end of this opening the metal was stretched almost to the breaking point.

This accident emphasizes several facts of importance in connection with the safe operation of steam boilers. First, it shows the need of observing the gauge glass, and testing the water level by trying the gauge cocks before stirring up the fire. It also demonstrates the danger of starting the feed pump when the gauge indicates that the water has fallen below the safe working level.

At such a time the natural impulse is to pump more water into the boiler as quickly as possible; but this practice is distinctly dangerous and should never be followed. The violent strains caused by the chilling action of cold water on the overheated metal, when added to the stresses already existing in consequence of the pressure in the boiler, are quite likely to cause something to give way. Hence the thing to do when low water is observed is to cool off the boiler gradually, and with as little disturbance as possible.

To avoid accidents due to low water in boilers we recommend to all boiler attendants that the following suggestions be kept in mind constantly:

Before starting up in the morning, make sure that the gauge glass shows the water to be at the right height. Blow down the water column next, and see that the water promptly returns to its proper level when the blow cock on the column is closed again. Try the gauge cocks also, and see that the water level as indicated by them agrees with that shown in the glass.

If the water is low, do not introduce feed-water, and if the feed pump (or injector) is running, stop it immediately. If the boiler is one of a battery, shut off the feed pipe running to it, and close the stop-valve in the steam pipe leading from the affected boiler to the steam main. As soon as these things have been done, cover the fire with a thick layer of ashes. If ashes are not handy, or if there is but a small quantity of them available, shovel in fresh coal, taking care to cover the fire at every point, until the boiler is effectively screened from the hot fuel on the grates. It is far better to bury the fire in this way than to haul it out of the furnace, because a great deal of heat would be given off to the boiler before the hauling could be completed.

Remember that the boiler has shown its ability to withstand the stress under which it was operating when the water was found to be low, and proceed on the theory that the thing to do is to reduce this stress gradually and without any sudden change of any kind whatever.

—*Travellers Standard.*

The Federal Engineering Co., Ltd., 127 John Street, Toronto, have arranged with the Thomson Gordon Co., Hamilton, for the latter to act as their distributing agents in Hamilton and vicinity for Scandinavia and Lanco Balata Belting. The Thomson Gordon Co. will carry a stock of these beltings in Hamilton.

A Course of Instruction for the Graded Certificate

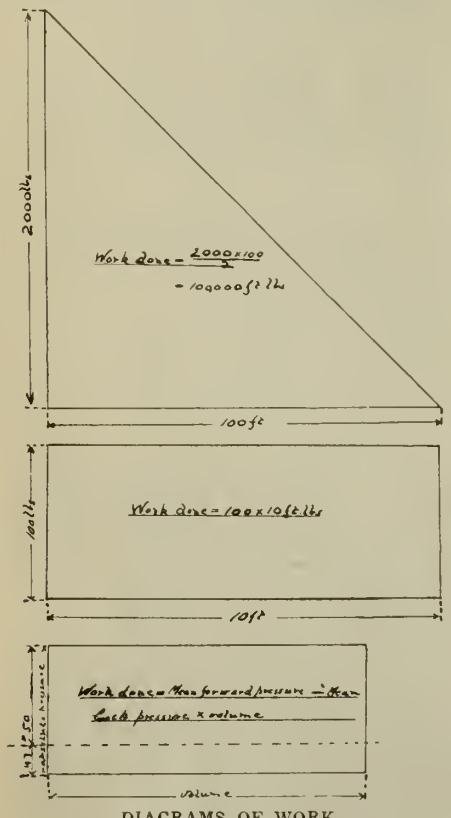
We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE have seen how steam expands according to Boyle's law that pressure multiplied by volume is always a constant to a certain extent. We can now go on to explain the diagram of work, and its application to the action of steam on the piston of an engine.

The Diagram of Work

It has already been explained that work is the product of force by the displacement of the force, or the distance through which the force acts. That being the case, the amount of work done by a force can be represented by a diagram, in which the vertical ordinates represent force, and the horizontal lines



DIAGRAMS OF WORK.

distance. For instance, if we have a force of 100 lbs. acting through a distance of 10 feet the product of force by distance will represent 1,000 foot lbs. If we now draw a line to scale representing 10 lbs. vertically and another to scale representing 1,000 feet horizontally and complete the parallelogram, the area enclosed will be equal to 1,000 ft. lbs., as shown by the illustration. If the force is not a uniform one, but varies from the beginning to the end of the displacement, the diagram may become curved or triangular. Suppose we had a chain

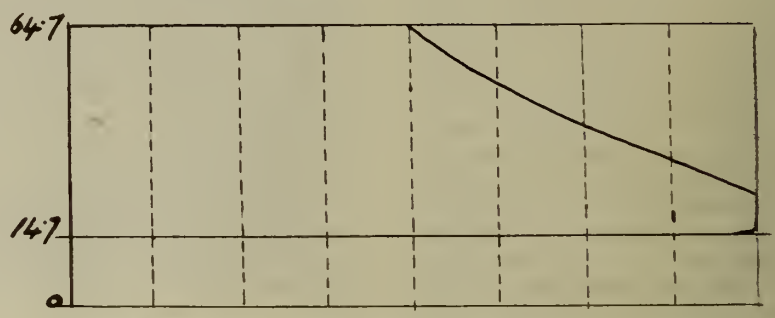


DIAGRAM SHOWING EFFECT OF CUT OFF AT HALF STROKE

that weighed two thousand lbs. and was 100 feet long, hanging vertically, and had to haul it up to the level of the top of the chain. The centre of gravity of the chain would be at a point 50 feet down, and the work done in lifting the whole chain would be 50x2,000 lbs., or 100,000 ft. lbs. Suppose the chain to be lifted 10 feet, the work done would be 2,000 plus 1,800, divided by 2, which would be 1,900x10, or 19,000 foot lbs. The next ten feet the weight lifted would be 1,700 lbs. and the work done 17,000 lbs. This is because, although when we start to lift the weight is 2,000 lbs. the weight decreases uniformly as the chain is hauled up. If we then take an average between the weight at the start of the lift and the weight at the finish and multiply by the height lifted we get the work done at any desired amount of lift. Thus if we take the two extremes we have 2,000 x 0 divided by two gives 1,000, and this multiplied by the lift is 100,000 ft. lbs. The diagram representing this would be a triangle, and the area would, of course, be the base multiplied by half the height. In the case of steam expanding in a cylinder the pressure is varying throughout the stroke in such a manner that the diagram becomes a figure with irregular curved sides, and the area is found by taking a mean of the various heights of the ordinates drawn to meet the curve from the line of zero pressure. If we take a diagram from a pump cylinder or a non-expansive engine the diagram is almost a parallelogram, but where we have steam cut off at any time before the end of the stroke, we get the curve due to the expansion of steam according to Boyle's law. If the height of the ordinates, that is the average height, represents pressure, this will be the mean effective pressure on the piston, and as the length of the indicator card represents the stroke of the engine to another scale, the diagram represents force displacement, and its area the work done, in foot lbs.

The Indicator Diagram

We can now take up the study of the indicator diagram and will take in the first place a diagram from a non-expansive engine, exhausting into the atmosphere. The vertical lines represent pressure, and the horizontal lines volume. Suppose that we have a cylinder taking steam at 50 lbs. gauge pressure and carrying it the full length of the stroke, when the exhaust passage opens and allows the steam to escape. If the stroke of the piston is two feet and the diameter of piston 11.27 inches, which is equal to 100 square inches area, we will have a force of 50 lbs. x 100, or 5,000 lbs., acting through a distance of 2 feet, and the work done will be 10,000 ft. lbs. Now we have said that the gauge pressure is 50 lbs., and as we always measure pressure from the zero line the absolute pressure would be 64.7 lbs., acting on the piston. As we are exhausting against the atmospheric pressure the actual effective pressure will be 64.7—14.7 or 50 lbs. We will see later more exactly how the mean effective pressure varies according to the amount of back pressure during the exhaust stroke of the piston.

Now, suppose we take the same engine and cut off the steam after the piston has travelled, say, half the whole stroke. The steam used will be only half that of the previous example, when it was carried throughout the whole stroke. Let us see how the work done will compare. In order to do this we must construct the theoretical curve of expansion and find by erecting ordinates the average pressure throughout the stroke, or else we can ascertain it by the calculation of pv equals constant. We can do the latter easily, and we find, if we divide the card into 8 parts, that the product of pv at half stroke will be 64.7 x 4, or 258.8. At the next point after cut-off the pressure will be 51.76, at the 6th point 43.13, at the 7th point 36.97, and at the 8th point 32.35. Adding these together and dividing by 8 we get the average

pressure throughout the stroke of 52.81, and subtracting from this the back pressure we get 38.17 as the mean effective pressure. The work done will be 38.17 x 100 x 2 = 7,634 ft. lbs. Thus we see that by cutting off at half stroke we have obtained for just half the weight of steam more than three-quarters the amount of work. We must not run away with the idea from this that expansion can be carried to extreme limits with benefit, because if we cut off so early in the stroke that the pressure falls below the atmospheric line in a non-condensing engine, then the piston will have to perform work against back pressure before reaching the end of its stroke, or in other words, the area of the diagram will be reduced. Suppose we take an instance: Taking again the same cylinder let us cut off the steam at one-eighth stroke. The result will be that the expansion curve will drop below the atmospheric line before the piston reaches the end of the stroke, and that

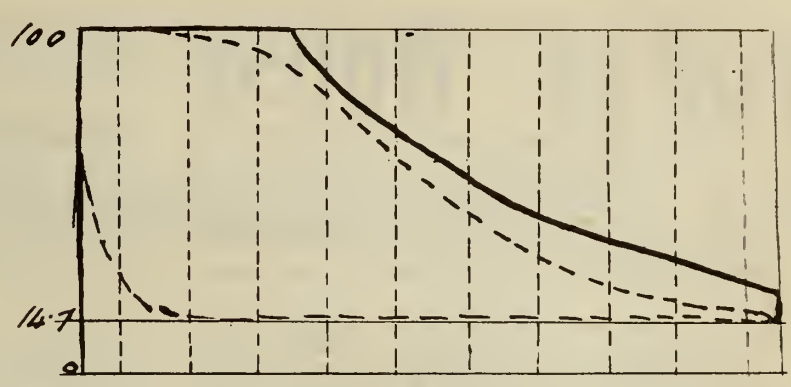

DIAGRAM SHOWING DIFFERENCE BETWEEN ACTUAL AND THEORETICAL CARD.

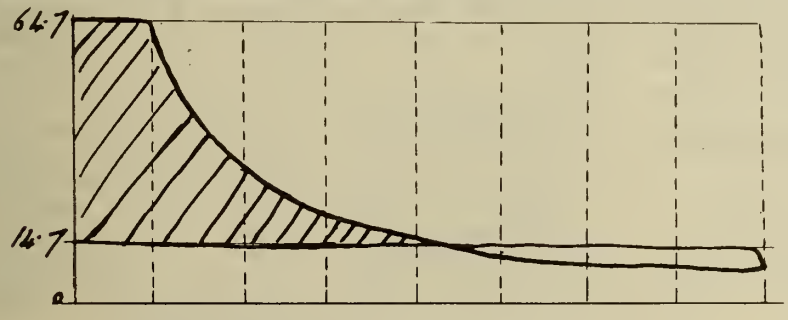

DIAGRAM SHOWING EFFECT OF TOO EARLY CUT OFF.

much work will be negative, as shown on the accompanying diagram.

The actual diagram taken from an engine is not only a means of finding out the work done per stroke, but is also a guide to the distribution of the steam in the cylinder, and the four leading points of that distribution. These are admission, cut-off, release, and compression. These four points are controlled by the movement of the slide valve, and the position of their occurrence tells us whether the valve is set correctly or otherwise. We will deal with valve setting and the different types of valve gears in another article.

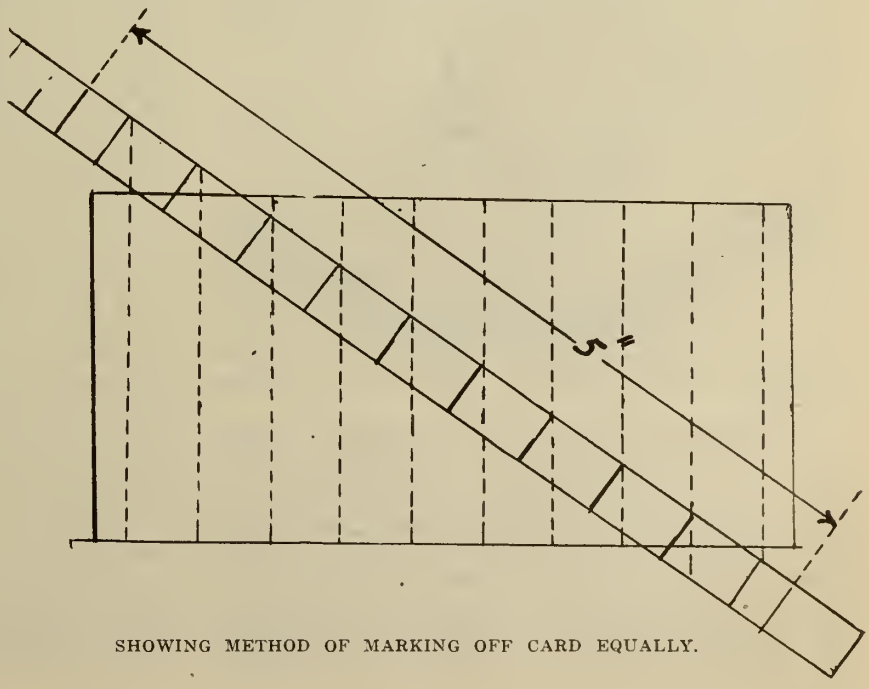
The form of the actual indicator diagram will differ considerably from that of the theoretical diagram, as instead of the sharp corners we shall have rounded corners, and the curve of expansion will fall below that of the theoretical curve. The degree of rounding at the corners of the card will depend on the setting of the valve and the form of valve gear used. The degree of closeness achieved by the actual curve to the theoretical curve will be affected by the degree of moisture in the steam.

In measuring the card for the mean effective pressure it is usual to divide the card into ten equal parts and measure the effective pressure at each point, add the results together, and divide them by ten. The mean effort on the stroke will be the result of the mean effective pressure multiplied by the area of piston and the length of stroke. On the crank side the area of the piston rod is sometimes deducted from the area of piston, but unless very exact results are to be obtained, this is not necessary. The mean effective pressure multiplied by area of piston and stroke gives the foot pounds of energy and this multiplied by twice the number of revolutions per minute gives the work done in foot pounds per minute. This divided by 33,000 gives the horse power. This is usually expressed by the formula

$$\frac{PxLxAxNx2}{33000} = H.P.$$

where P = Mean effective pressure.
L = Length of stroke in feet.
A = Area of piston in square inches.
N = Number of revolutions per min.

A good way of obtaining the divisions on the card is to extend the lines at each end up and down, and lay a rule diagonally across the card, making the points where the line touches the rule exactly five inches. Then make a mark ¼ inch from the line, and the others ½ inch apart over the five inches. By dropping perpendiculars from these marks the card will be accurately divided. The illustration will make this plain. This subject will be continued in further issues.



SHOWING METHOD OF MARKING OFF CARD EQUALLY.

Our Question Box, Operator's Point of View, New Equipment.... 31

AN interesting paper on the commercial possibilities of peat as a fuel was read recently before the Engineering Institute in Toronto, and some of the facts brought to light are of deep interest in view of the general fuel situation. The author of the paper was Mr. Wynne-Roberts, and deals with the formation of peat generally, and with the methods adopted by the Peat Committee, a body appointed by the Government of Canada and the Government of Ontario conjointly.

Peat is produced by the slow decomposition of vegetable matter in the presence of water, and the exclusion of air. The peat as it is found in the natural state in the bog is a mixture of water and disintegrated vegetable matter of varied origin and the weight of the water is from 87 to over 90 per cent. of the total weight of the matter. It is this large water content which presents the greatest obstacle to the utilization of peat as a fuel and the work of the committee has been directed along the lines of discovering a means of drying the peat so that it could be commercially handled. That is where the cost of drying would not exceed the value of the fuel as a heating medium.

It is pointed out that peat is an exceedingly variable substance, as not only will there be a difference between two adjacent bogs, but there will be variations in the different layers of the same bog. These variations, while not affecting the peat as a fuel generally, will affect it when it is to be used for some specific purpose. With increase in age and depth of the bog these differences become less and finally disappear completely. This variation is noticed in the specific gravity of the peat found, which ranges from 0.1 to 1.06. The higher specific gravities occur of course where the peat is more thoroughly decomposed. Another feature is that the ash content, although usually low, may in some cases be so high as to render the peat valueless as fuel. The normal peat does not present any great difficulty as far as ash is concerned. A typical analysis of Canadian peat gives carbon 56 per cent., hydrogen 5.2 per cent., ash 6 per cent., and the oxygen, nitrogen and sulphur make up the balance 32.8 per cent. The calorific value of dry peat is from 8,000 to 9,000 B.t.u. per pound in Canada, though in other countries, notably Ireland, it runs up to 10,000 B.t.u. These values of course apply only to dry peat and as this is never available it is only the net calorific value than can be reckoned on.

The paper points out that various methods have been tried of drying the peat out, one of the first of these being the "Ekenberg Wet Carbonizing Process," in which process the peat was heated under pressure in a closed retort. This effects a chemical change, the carbon content being increased while the free oxygen combines with some of the hydrogen, forming water and thus increasing the water content. As no gases are evolved during the heating, none of the combustible components of the fuel are lost. The peat is then subjected to pressure, when some of the water is separated, and the remaining water has to be separated by artificial heating. In the opinion of the author, this process is not commercially possible. Efforts have been made to separate the bulk of the water by artificial drying, by direct application of heat, or by the passing of heated air over and through the mass of peat to be dried, or again by blowing large quantities of air at atmospheric temperature through it. None of these methods are successful, because there are not enough heat units in a pound of peat containing 90 per cent. water to evaporate the water alone (assuming a drier efficiency of 100 per cent.). Before drying by the application of artificial heat, or by any method whatever, can be attempted, the water content must first be reduced to 50 per cent. or below. If it be reduced to 50 per cent., then for every ton of wet peat containing 200 lbs. combustible substance and 1,800 pounds of water, 1,600 pounds of water must be removed by other means than the employment of artificial heat.

The method now being employed by the Peat Board is known as the wet process and the peat obtained is termed machine peat. In this method the peat is first cut by a machine and afterwards transported to the hopper of a second machine which grinds it down to a fine pulp. This pulp is then taken to a specially prepared portion of the bog and spread over the surface where it is left for the sun and wind to dry it. When sufficiently set the peat is cut transversely and longitudinally into blocks, which when containing 25 per cent. to 30 per cent. moisture, have the dimensions of ordinary building brick. Peat made in this manner is clean to handle and can be burned in an ordinary stove or fireplace with little soot or ash. The ash is finely divided and no clinkers are made, while the fuel is very easy to ignite. For the production of steam the water content should not exceed 30 per cent., and 25 per cent. will give the best results. If the peat is to be manufactured into briquettes it should be dried down to 15 per cent. or lower. The author in concluding his paper draws attention to the large area of peat bogs that are in existence in Europe and on this continent. Canada has 37,000 square miles covered by peat bogs, a large portion of which is suitable for making fuel. In the more inhabited parts of the Dominion there are 12,000 square miles and assuming that this 12,000 square miles has an average depth of 6 feet, there would be sufficient peat to manufacture 9,000,000,000 tons of 25 per cent. moisture peat.

There can be no question that the possession of such large areas of potential fuel has an important bearing on the fuel question in general. The work that the peat committee is doing has a great value to the province and the Dominion in general and is deserving of every sympathy and support. The paper of which such brief extract is given above is crammed full of interesting information on this interesting subject and should be read by all those who have thought or are thinking of the fuel question in a serious manner.

The Operators' Point of View

Methods of Ice Protection For Turbo Hydraulic Plants

By F. SWEET

TO start now and preach preparedness for ice troubles for the winter of 1922 is hardly untimely.

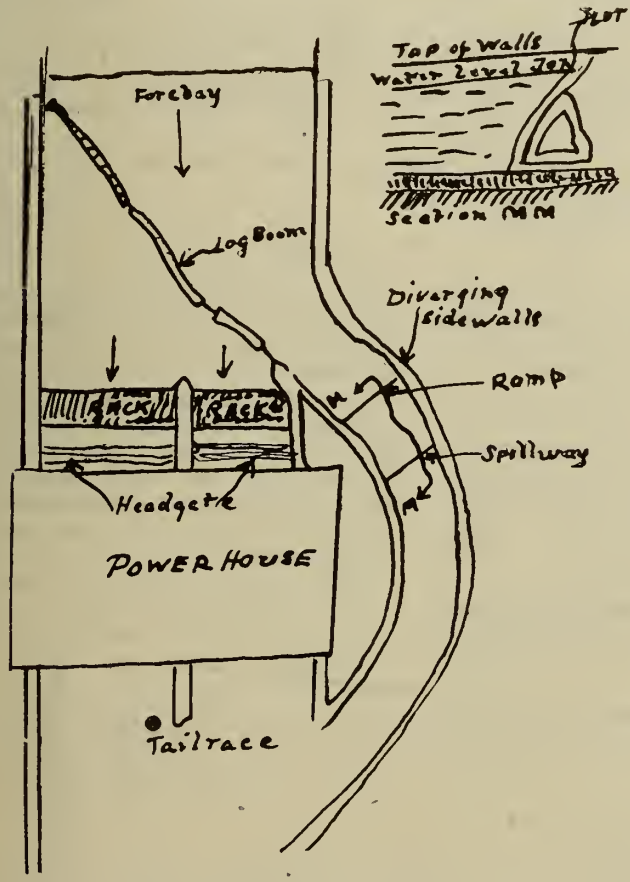
To be brutally frank about it, all such preparations should be fully completed before Labor Day especially if any concrete work be included in the program. Eleventh hour work and repentance are both dangerous, the former where it involves concrete for ice protection, because the concrete does not have the necessary time to age and attain safe values of strength. This last remark concerning strength may appear a trifle dubious or far-fetched to some, but those who have seen what tremendous forces are met with in comparatively small ice jams and have seen the effects produced, will not be inclined to minimize the element of safety.

The field of this article is ice protection for the small and medium sized plant. As a rule the larger plants are provided with suitable means of protection when they are being designed, and such design is usually placed in the hands of competent engineers. Smaller and medium sized plants are usually built first and designed later. The owner often does his own engineering, drawing on his rich experience of perhaps thirty or forty years in human nature, and like the translator who learned his Spanish from cigar bands, he "gets by" somehow. So it is usually after a hard winter's tussle with ice troubles that some earnest thought is given to "what we'll do for next winter."

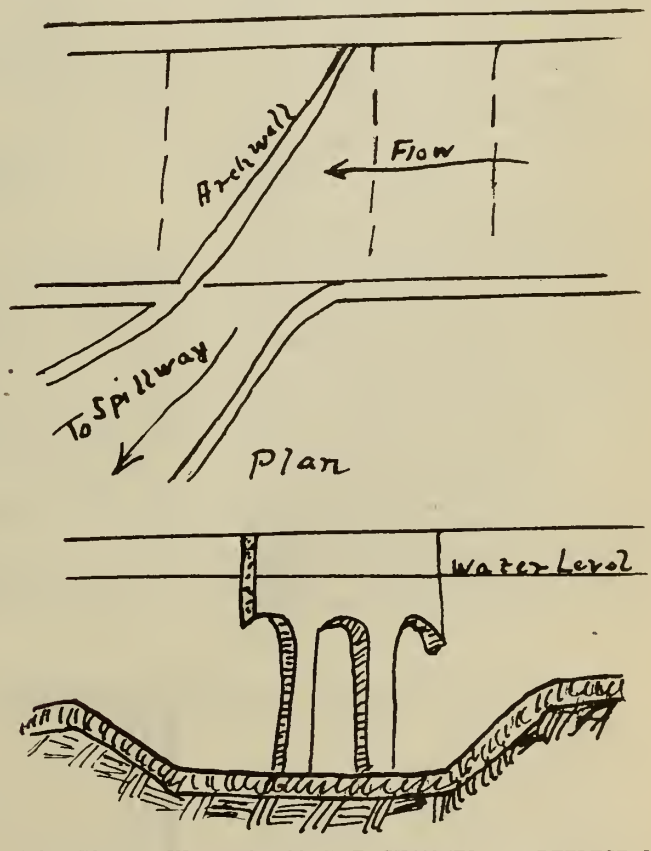
There are two methods of handling the ice problem, just as there are two ways of treating a headache. If you have a headache, are you going to take a powder and relieve the headache or are you going to get at the cause of it? The first can be called palliative, the second, preventive. The second method, that of prevention, is the only logical treatment in the case of either headache or ice troubles. To get rid of the ice up at the forebay and prevent its passing through the plant is the one best bet.

As to prevention, there are the following, which have shown their worth by actual operation:

(a) A log boom placed across the channel at about 45 deg., the discharge end of which deflects or guides the floating ice into a suitable receiving basin, whence it can be discharged over a spillway or sawed up for storage. If the spillway mentioned is properly design-



LOG BOOM STRETCHED ACROSS THE FOREBAY TO BY-PASS ICE.



ARCH WALL BUILT ACROSS THE CHANNEL TO DEFLECT ICE ACCUMULATIONS.

ed, the pressure of accumulation will force the ice over the spillway apron without manual aid, save perhaps in the case of very large pieces.

(b) A submerged arch, or series of arches, inclined to the channel width at not less than 30 deg., the crowns of the arches being submerged from 30 to 42 inches, according to climate. As in the case of the log boom, the ice is to be deflected or guided into a receiving basin and from there discharged over a spillway.

(c) Where Taintor gates are used in cases of waste spillways, or in cases where such gates are used as the means of draining the turbine pits, conditions will arise that will cause the gates to be solidly frozen in. In such cases the plant cannot be started; so it is a good practice to box in the top and sides of the gate nearest the power house, and to put in a generous sized steam coil inside of the gate. This will melt the ice around that one gate, and as soon as the flow is started, the other gates will thaw out successively.

(d) In very cold climates, ice will form around the speed rings of the turbine, and clogging up of the water passages will soon follow. This has been prevented by putting two coils of pipe around the crown plate of the turbine and connecting the two by means of vertical drop legs placed just outside of the guide vanes in the speed ring.

(e) I understand that some effort has been made to use travelling screens to keep the turbine pits free of ice, but unfortunately data on their cold weather performance are not available.

The log boom is made up of good sized tree trunks, of length to suit the location and connected by means of pieces of heavy chains, usually about 3 feet long, firmly spiked to the log ends. Figure 1 shows the log boom across the channel. The ice as it comes downstream is deflected into the receiving basin and the pressure of accumulation will force the blocks over the ramp of the spillway. From the spillway, the disposal will depend on the topography of the site. Where the entire river discharge passes through the plant, the ice spillway can be made as shown in Fig. 1, the spillway discharge going into a tumbling bay connected with the tailrace, the effect being that the ice merely by-passes the plant. The spillway, somewhat better shown in section M, should have a concrete slap ramp extending up to the normal winter water stage, and above the slab slots should be cut in the side walls so that the water can be saved by putting in stop logs in case the water should be abnormally high. To make the receiving basin self-clearing and avoid ice jams therein the side walls should diverge about 1 foot in each 10 feet, so that the channel increases 1 foot in width in each 5 feet of run.

In some cases in the colder climates, a log boom alone will not be sufficient. The logs, at the most, will probably sink only 12 to 18 inches below the water surface and quite a few good sized ice chunks will be carried under the logs by the current. Here the submerged arch will give good results alone, although I recommend that it be used in connection with the log boom. Refer to Figure 2. Such an arch wall should be set at not less than 30 deg. with the width of the channel and like the log boom it should guide the ice over a spillway or into a receiving basin. Since the immersed section of the arches, together with the piers, take up a considerable portion of the cross-sectional area of the channel, the channel should be made correspondingly deeper at that point.

As to the steam-heated Taintor gate, it is merely the conventional form boxed in on top and the sides. The bottom must be left open so that the water can freely come in touch with the heated air of the interior. The steam inlet should come in at a high point and be connected with the coil by flexible steam hose long enough to permit opening the gate fully. The coil should be drained by gravity and the returns trapped or gravitated to the boiler. As to the size of the coil, it must be said that it is wise to err on the side of generosity. Strictly speaking, the coil is used for starting the flow only, and the larger the coil the sooner the gate will be thawed out.

The same reasoning applies to the coils around the turbine speed ring, except that occasions may arise when it is necessary to use these continuously.

STRAIGHTENING ROTOR SHAFT

Recently I was given a job straightening a 2 in. rotor shaft, which was bent right at shoulder on pulley end, and as I thought it would be next to impossible to straighten it without taking shaft out of rotor, and as it is quite a job to take same out and place it again, I did it in novel way, which may interest some of our engineers.

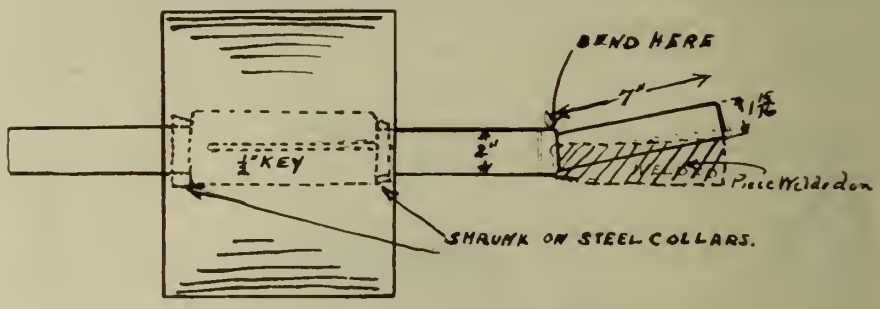


DIAGRAM OF ROTOR AND SHAFT.

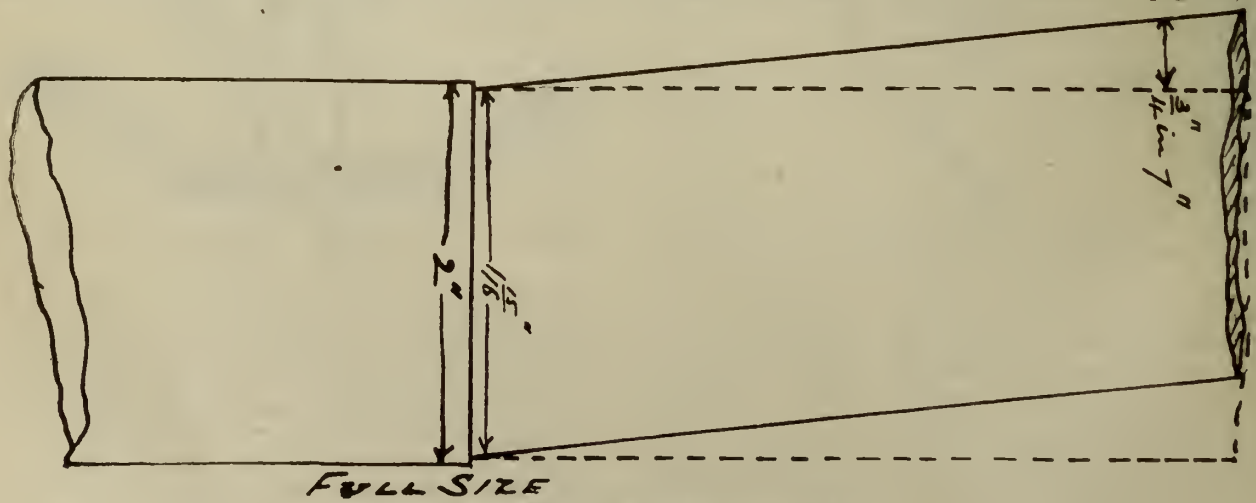
The rotor shaft in question was bent in transit by the railway company and was out about ¾ in. As our readers well know only .008 inch is allowed between stator and rotor laminations, so it is seen that rotor shaft must be perfectly straight.

I did not care to heat it nor hammer it, so we had one side built up with elec-

(Continued on page 36)



FULL SIZE SKETCH SHOWING AMOUNT OF BEND.

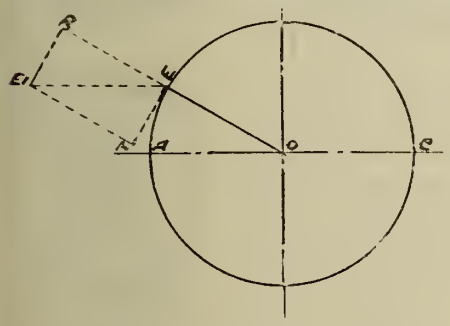
OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

TURNING MOMENT ON CRANK

Question.—What is the turning effort on a crank when crank is at centre of stroke?

Answer.—The turning effort for different positions may be found from a diagram. Thus, suppose the pressure is uniform and the connecting rod is of infinite length, construct the following diagram: Let the radius of circle OA represent to scale the load on the piston.



TURNING EFFORT BY PARALLELOGRAM.

When the crank is at OA or OC there is no turning effort, while from OA to OB the turning effort increases from O to a maximum. Suppose the crank at OE, then the force on the crank pin can be resolved into two forces, one acting to the centre of the shaft and one at right angles to it. Then the line TE measures to scale the tangential force acting on the pin, or the turning effort on the pin. This multiplied by the length of crank gives twisting effort on the shaft.

When the crank is at right angles suppose the rod to be of infinite length, then the load would be equal to the load on the piston. As the connecting rod is not of infinite length, but makes a definite angle, the load on the crank pin will be equal to the total load multiplied by the cosine of the angle the rod makes with the centre line of engine.

This can be shown diagrammatically: In the following diagram let P = load on piston, R = thrust on connecting rod, OC = crank, OD centre line at right angles to centre of engine, and OV a line perpendicular to R through centre line of shaft. Then the thrust on the rod R is equal to PCosA, and the twisting movement on the crank shaft is equal to Rx OV. The pressure will, of course, have to be determined for the various positions of crank from the indicator diagram, but when cut off takes place at half stroke the maximum pressure on the pin and the maximum turning movement on the shaft will occur at half stroke. We have neglected the effect of friction and of the acceleration and inertia of the moving parts.

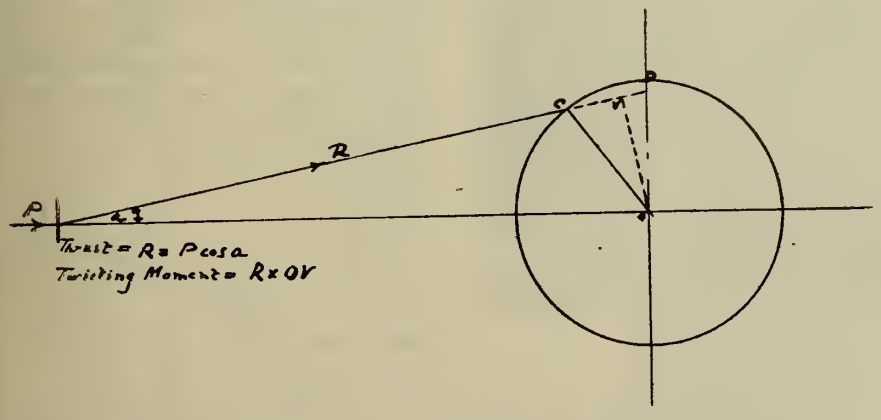
THE V NOTCH

Question.—How can I measure the flow of water over a V notch?

Answer.—If the flow is steady $q = \frac{4}{15} k w h \sqrt{29h}$ cubic feet per sec., where

w = width of notch in feet.

h = head of water from apex of V in feet.



THRUST ON ROD IS EQUAL TO PcosA. TWISTING EFFORT ON SHAFT = RxOV.

29 = 64.4 (gravity).

k = constant from .59 to .62, according to the angle of V, .59 being for a right angle.

When the angle is a right angle, then $q = 3h^2\sqrt{h}$ cubic feet per minute, h being in inches.

ANOTHER GRADED CERTIFICATE QUERY

To the Editor, Power House.

Can a superintendent of a factory who holds a second-class certificate take charge of the boiler room, leaving a man who has no certificate to work it? To the writer's knowledge the superintendent has but little time through the day to see how things are going on (in this case). This is a high pressure boiler. There is another factory here where the superintendent has a certificate and the hand man around, who has no certificate, but does the firing if this is allowed and there is no law for it. What is the use of the present system of graded certificates?—Woodstock, Ont.

OTTAWA LODGE, C.A.S.E.

Ottawa Lodge, No. 6, C.A.S.E., held its second open meeting on Thursday evening, Dec. 23rd, which had a large attendance.

Bro. C. V. Clarke, chairman of the Educational Committee, gave a very interesting paper on boiler-room efficiency, dealing with different systems of firing to give best results. He also dealt with the proper way of handling returns to avoid loss, which always amount to dollars lost when not properly handled.

Bro. G. I. Scott, chief engineer of the Ottawa Electric Co., also gave an interesting address in well chosen words on the proper handling and use of the rurometric condenser, explaining how troubles occur and how to overcome them. We congratulate Bro. Scott on securing his first-class certificate. I think he is first in Ottawa to receive a first.

R. E. RODNEY, Rec. Sec.

We have received a copy of the revised edition of "How to Build Up Furnace Efficiency," written by Jos. W. Hays, the well-known combustion engineer. This is the sixteenth edition of this well-known little book. It contains all the original matter and some new cartoons have been added. There is also an appendix on oil, wood, gas and other fuels. This book puts the subject of combustion in a most intelligible and readable manner, with the touch of humor that appeals to most of us, especially when introduced to lighten such a practical subject. It is chock full of sound advice and well worth the price, $1.50. It is published by Jos. W. Hays, Michigan City, Indiana.

Progress in New Equipment

THE GODFREY CONVEYOR

THE coal conveyor illustrated and described here is made by the Godfrey Conveyor Company, Elkhart, Indiana, U.S.A., represented in Toronto, by M. A. Kennedy, of 110 Richmond street W.

The principle of the Godfrey system is to get coal from bottom dump cars into a chute underneath the railroad track, the chute conveying it by gravity into a bucket in which it is elevated and carried to a storage pile or an elevated bin or conveyance.

The mechanical units consist of a bucket of approximately one ton capacity, a two-drum reversible hoist operated by electric motor or other suitable power, a trolley operating on a monorail or cableway, a steel chute with gates to control the flow of the coal, and the necessary sheaves, cables, etc., for making the connection of the various units.

The two types of overhead track, namely, the I-beam and cable-way, make the equipment easily adaptable to any one of a large variety of conditions. The principle and operation of both types is the same, while the choice depends entirely upon the local conditions which have to be met.

The entire operation is controlled by one man stationed at the hoist, which is located near the mouth of the track chute. This enables the operator to open and close the gate of the chute which controls the flow of coal into the bucket.

A hoist of special type is employed. This hoist is mounted on a cast iron base and is of ample proportion to carry the load. The operation of the two drums on the hoist is controlled by clutches, insuring speed and safety with ease of operation. The main or hoisting drum is used to elevate the bucket to the required height and the traction drum moves the trolley in either direction on the conveyor track. The trolley supports the hoisting cable on which the bucket sheave rolls; this enabling the man at the hoist to lower the bucket at any desired point under the conveyor track without making any changes or adjustments on the equipment.

A TYPICAL INSTALLATION

The coal when emptied out of the car falls by gravity through a specially constructed steel chute into one ton conveying bucket suspended or guide rails in a pit at the side of the track. When the bucket is filled the hoist operator closes the gate of the chute, thereby shutting off the flow of coal into the bucket. The hoisting drum is then engaged, which raises the bucket to the required height. The operation of the traction drum of the hoist then moves the bucket along the conveyor track to the point where the operator wishes to dump the coal.

The bucket is then lowered until it comes in contact with the coal pile. The contact releases a latch on the bottom of the bucket, opening the two doors and the coal flows gently out without any breakage and consequently no degradation. This means of tripping the bucket when in contact with the pile is a patented feature of Godfrey equipment. The bucket can be lowered or hoisted at any point, no stops or trippers being required. The largest lump as well as the finest screenings can be handled.

The coal is emptied as the bucket is raised and the bottom closes automatically. The bucket then travels on the monorail back to the pit for another load.

Coal can be stored to any height desired, bins or storage space filled to capacity with no trimmings, or wagons can be loaded directly from the cars with no breakage; all this by the labor of one man.

Ashes, sand, crushed rock, gravel and similar materials can be handled in the same way and as cheaply. In many cases the same equipment is used to unload, store and convey coal to the boiler room and remove ashes to cars or hoppers.

Coal can be reclaimed from open storage; or flat bottom cars unloaded by changing the conveying bucket for a "hook-on" clam shell bucket. Lumber, logs, or baled material can be handled by substituting grab hooks for the bucket. The possibilities for handling all kinds of manufactured articles or raw materials are practically unlimited.

The installation is very simple, due to the fact that the mechanical units are shipped assembled. The erection work consists of placing concrete for the track hopper and pit, also concrete bases for the A-frame which supports the monorail track and the hoist base. Where

15 Sales Offices Backed by the 100% Standard of Quality

THE Canadian Fairbanks-Morse Company Limited reaches out to you through its sales houses and offers the service and satisfaction that is assured by its 100% standard of quality and service.

To be able to turn to an institution that dominates its field in the industrial world is to safeguard the character of the merchandise you buy. To deal with an organizationthat is doing business at your very door puts upon the man you know that "responsibility which is the conscience of business."

Every one of these 15 offices has been established to bring to you the full advantages and benefit that have made The Canadian Fairbanks-Morse Co. Limited a national institution. Here in these offices is offered everything mechanical that your business requires — they centralize your purchasing—group your orders—bulk your shipments and send but one invoice. And when you buy from The Canadian Fairbanks-Morse Co. Limited you are guaranteed the 100% standard of quality and service in product and organization.

Make our nearest office your buying centre—our catalogue is your buying guide —our 100% quality seal your guarantee.

The Canadian Fairbanks-Morse Co., Limited

Canada's Departmental House for Mechanical Goods

Halifax St. John Quebec Montreal
Ottawa Toronto Hamilton
St. Catharines Windsor Winnipeg
Regina Saskatoon Calgary
Vancouver Victoria

2

a cableway is used the supporting masts are set on concrete bases. The A-frame supports for the monorail may be constructed of wood. However, a special steel structure may be obtained and is recommended for permanency.

The hoist and operator do not travel on the monorail with the load, enabling a lighter construction to be used.

The operation is not confined to a straight line but can be made to include curves. It can be installed parallel to the railroad siding or at any angle thereto. The height of the track can be made to suit local conditions and storage requirements.

The above photograph well illustrates the Godfrey system. This installation represents the latest type of steel construction and is built at right angles to the siding.

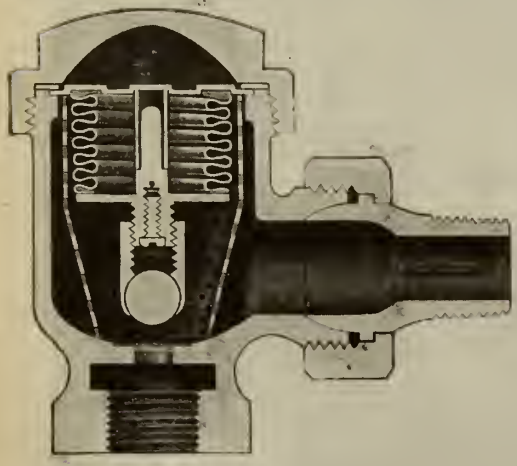
Coal is conveyed directly from cars to storage or chutes for stoking kilns. By interchanging buckets and substituting a reclaiming bucket, coal is picked up from open storage piles and conveyed to the chutes or direct to boiler room.

This particular installation serves kilns at some distance from the siding, cheaply and efficiently, and will store a large quantity for winter use.

The operation of the hoist does not require a skilled mechanic.

A NEW RADIATOR TRAP

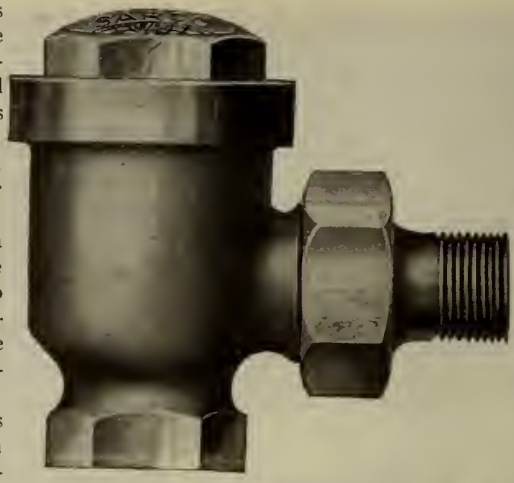
The Sarco Company, Inc., New York, has just placed on the market a new valve for radiators and steam heating



SECTION OF TRAP

service. This is a modification of the steam trap Sarco and approaches in design the standard types of radiator trap valves, while retaining the characteristic Sarco features.

The body is a heavy brass casting and the expansion element a Sarco spiral bellows. The valve head is a ball freely turning in a socket and a strainer of ample capacity is provided in the valve casing. This trap is factory adjusted. It can be used for any vacuum or for low pressure up to 20 pounds. It is claimed that the large discharge areas and the



OUTSIDE VIEW

movement of ¼ inch insure a larger capacity than any other type of thermostatic radiator valve can give.

STRAIGHTENING ROTOR SHAFT

Continued from page 2

tric arc welding process, then rotor was set up in lathe, welded end in steady-rest, faced and new centre put in, and then shaft turned to 1-64 oversize and then ground to exact size; it was then impossible to tell any defect nor that shaft had ever been welded. Operation took six hours and rotor never got hot enough to melt solder out of rotor rings.

ERNEST QUIST.

The idea shown above is quite satisfactory as regards truing the shaft. It does nothing, however, to relieve the strain set up on the fibres of the shaft at the shoulder, where it was bent. We think that the rotor could have been protected by a shield from radiant heat and the shaft warmed at the bend by a blow torch and straightened up by pressure. It could then have been heated to a dull red for two or three inches each side of the bend, and allowed to cool, after which it could have been trued up in the lathe. The insulation would not have been damaged in this way, and the molecules of the metal would have been returned to their normal condition. As it is a certain amount of initial stress is present when no load is on the shaft, and this the welding would not help. We would like to hear some opinions from our readers on this.—Editor.

M. A. Kennedy, Ltd., of 110 Richmond Street W., Toronto, have accepted the agency for Ontario of the Godfrey Conveyor Company, Elkhart, Indiana, U.S.A. This firm specialises in the manufacture of a coal handling conveyor, consisting of a hoisting and tractor drum, and a series of supports carrying either cable ways or I beams. The coal is transported in one ton buckets, which are so designed that they are tripped when the bucket comes in contact with the coal pile. This eliminates or reduces to the smallest possible degree the breaking of the coal by dropping a long distance from the bucket to the pile. It is claimed that the whole apparatus can be handled by one man, and used for loading, unloading, and reclaiming coal from storage. There are a large number of these equipments in use, and giving satisfactory service.

CATALOGUE

The Mason Regulator and Engineering Co. have issued a very handy catalogue in a form that can be hung up like a calendar and shows at a glance the name of all the lines handled by them. The particular article or piece of apparatus, which is interesting the buyer at the moment, can be turned to immediately, without any loss of time. The lines include the well-known Mason regulating and reducing valves, Reilly heaters, feed water filters, evaporators, Ashton safety valves and steam gauges, and other well-known power plant specialties.

We have received Catalogue F of the Ross Heater & Manufacturing Co., Buffalo, N.Y., illustrating and describing their various types of heaters. There are two general types, the instantaneous heater and the storage heater. In the first the water is heated as it is being used, while in the latter a certain storage capacity is provided to be drawn on in emergencies. Full descriptions of the different designs manufactured in both types is given, with tables of capacities and diagrams of installation layouts. Condensers, expansion joints, and air-jectors manufactured by the Ross Heater Co. are also illustrated.

Ready to Operate.—The new industrial plant of Machinery and Foundries, Ltd., Brockville, Ont., is almost ready for operation. General foundry and machine products will be turned out and special attention will be paid to the manufacture of power and hand pumps. The cost of the construction of the plant will be about $75,000.

Creosoted wood cannot be painted over successfully, because the oil quickly comes through the paint and discolors it. Although pressure treatments are the most expensive they are the most effective because they result in the greatest absorption and penetration of preservative. Roof planking should receive 8 lb. to 12 lb. of creosote per cubic foot, or ½ lb. of the salt if zinc chloride be used. Such treatment should add at least twenty years to the life of roof plank. Lumber should be cut to final dimensions before treatment. Whenever it becomes necessary to cut into treated timber the untreated wood exposed by cutting should be given two brush coats of creosote or some other preservative.

WATER POWER AND LOCATION OF PLANT

The presence of coal has been one of the most important factors determining the industrial expansion of various countries during the past hundred years or so.

This condition is gradually changing through the exhaustion of coal supplies. A recent article by G. H. Ashley, State Geologist of Pennsylvania, emphasizing the necessity of replacing coal by water-power, is particularly significant, coming from one who is well able to judge the situation in this great coal state. His statements are of special interest to Canada in view of the prediction that industrial supremacy will, eventually, pass from coal-depleted regions to areas where large water-powers are available. It is even pointed out that one way of keeping the industries where they are in the United States would be by the importation from Canada of enormous quantities of hydro-electric energy available on the St. Lawrence and at Niagara.

Mr. Ashley holds that: "The industrial East has maintained its supremacy because of cheap fuel and nearness to markets. Because of cheap fuel Pittsburgh can afford to haul iron ore from Minnesota. It does not take a seer nor even a scientist to point out that, if our present increased use of power continues, a generation will see the exhaustion of cheap fuel in the East."

"A review of the field today shows that, in several of the districts, practically all of the thick coal has been mined out, while in others it is possible to count the years to the time when the supply will be gone. It may be argued that, as the cost of coal increases, the manufacturing interests of the East will turn to water power. That argument leads to the question of the adequacy of the water-power of that region to take over the burden now carried by coal."

"In addition to the powers within the boundaries of the northeastern United States, there are large powers to the north in Canada. The St. Lawrence below the international boundary is estimated to have a potential horse-power of nearly 1,500,000, and the provinces of Quebec and Ontario have been estimated to have a maximum of 6,000,000 h.p. each, including that from Niagara and the St. Lawrence. Already 125,000 h.p. is imported into New York from Ontario, and a small amount is imported into New England. If all of the Canadian water powers were developed and Canada would allow the exportation of, say, one-half the power, or 6,000,000 h.p., it is probable that the northeastern corner of the United States could look forward to an ultimate utilization of not less than 10,000,000 to 12,000,000 water horsepower."

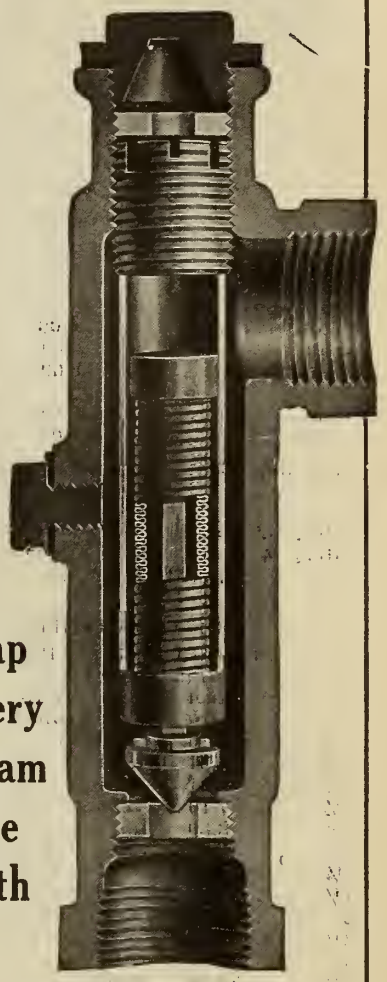
It need hardly be pointed out that the benefits accruing to Canada from the exportation of 6,000,000 horsepower would be relatively negligible. One large manufacturing plant using, say, 1,200 h.p., would employ more men than the water-power plants generating 6,000,000 h.p.

THE USE OF PEAT AS FUEL

In a lecture delivered by Professor P. F. Purcell before the Royal Dublin Society and published by the Fuel Research Board, it is stated that the total amount of peat used in Ireland lies between six and eight million tons per annum, as compared with 4¾ million tons of coal imported and 90,000 tons raised in the country. Irish peat has advantages in two respects, (1) the ash content is comparatively low, and (2) the nitrogen content is comparatively high. It is, therefore, a good peat for the recovery of sulphate of ammonia. Peat, generally speaking, contains from 90 to 95 per cent. of water, and part of this moisture cannot be pressed out owing to it being held by the colloidal matter in the peat. There are at present only two installations in Ireland where this fuel has been successfully employed for the generation of power. One is at Clifton, in Galway, where the Marconi Company uses 5,000 to 6,000 tons of air-dried peat to generate the power for the wireless station. The other is at Portadown, where the power for a linen factory is obtained from a producer gas plant using peat as the fuel.

In a paper dealing with the uses of aluminium for electric installations, Mr. E. O. Pannell, the author, states that aluminium can be drawn three times as far as copper without having to anneal it. The finished wire should indicate 58 to 62 per cent. of the conductance of copper wire of the same size, but it is usual to take 60 per cent. for this figure and a tensile strength of 24,000 pounds per square inch. Thus, if it is required to replace a copper wire on an overhead line with one of aluminium, the latter must have a 29 per cent. greater diameter and a 66 per cent. greater area. To increase the tensile strength and so permit a reduction in the sag of the conductor between the supports aluminium strands are laid around a core of steel wires. The steel wires are double galvanized and impregnated with fish oil to prevent corrosion. A cable of this type is about 35 per cent. heavier than aluminium, and costs, it is stated, 4 to 5 per cent. more; but it has a sag on long spans of 50 per cent. less, so that especially high towers are obviated.

Auxiliary Power Plant.—The Oakvillle town council are again considering the possibility of adding an auxiliary power plant to the present one in the pumping station. During the sleet and ice storm some weeks ago, the power supplied by the Dominion Power & Transmission Lines went off.



Trap Every Steam Line With a

SARCO

High Cost of Steam
Versus
Low Cost of Trapping

There was a time when steam was cheap. Not now. Now it costs more than at any time within a hundred years.

There was a time when all steam traps were expensive, big, cumbersome, troublesome things.

Not now. Now you can use the Steam Trap Sarco, which is small, low priced, absolutely efficient and reliable, and goes right on to any line anywhere.

Many an untrapped line steals the cost of a Sarco every week.

The Steam Trap SARCO relies on the expansion of a heavy hydrocarbon oil operating a Sarco Spiral Tube within a renewable cartridge. When steam reaches the cartridge, the trap closes and no steam escapes. When condensation collects the trap opens and discharges it.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

BELTING

4½—4-PLY NEW CANVAS STITCHED BELTing at 30 cents per foot. We carry a complete stock of belting, pulleys and mill supplies. Apply, mentioning "Power House," to N. Smith, 138 York St., Toronto.

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto.

WE HAVE A QUANTITY OF NEW RUBBER belting to sell at less than half price; will ship C.O.D., subject to inspection; new circular saws, good second-hand leather and rubber belting, wire cable, vises, chain blocks, garden hose, steam hose, rubber packing; send us your requirements; our quotations will surprise. Apply, mentioning "Power House," to The York Belting Co., 115 York St., Toronto, Ont.

GOOD INVENTIONS

ENCLOSED LIQUID FUEL COMBUSTION APparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented October 8th, 1918. Can be inspected at and for sale by H. W. Petrie, Limited, 131 Front St. W., Toronto.

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House."

SITUATIONS VACANT

WANTED—A1 GENERAL BLACKSMITH FAMiliar with mine and mill work; permanent position. Apply, mentioning "Power House," stating experience and wages wanted, to Moose Mountain, Ltd., Sellwood, Ont.

CHIEF DRAFTSMAN WANTED FOR ESTABlished engineering office in connection with extensive construction program for sulphite mill development; give full detailed information with references first letter; single men preferred. Apply, mentioning "Power House," to Riordon Co., Ltd., Mattawa, Ont., Can. (pfh)

EQUIPMENT

THE JOHN INGLIS CO., LTD., ENGINEERS and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention "Power House."

WE BUY IDLE EQUIPMENT OR MACHINery; call or write. Apply, mentioning "Power House," to H. W. Petrie, Ltd., Toronto.

HEATERS, PUMPS AND CONDENSERS, boilers, steam engines, tanks and stacks, transmission and elevating machinery, safes, vaults and vault doors; catalogues and specifications sent on request. Apply, mentioning "Power House," to The Goldie & McCulloch Co., Ltd., Galt, Ont. (pfh)

PORTABLE BOILERS—LOCOMOTIVE TYPE, on wheels, each 15 horsepower, with engines mounted on boilers; can get Government certificates for 90 and 100 pounds working pressure; cheap; also 40 horsepower, high speed Leonard automatic engine. Apply, mentioning "Power House," to Henry Engineering Co., 71 Bay St., Toronto. (pfh)

BOILERS AND POWER PLANT EQUIPMENT bought by the Henry Engineering Company (Henry-Rumgay-McBryde). Apply, mentioning "Power House," to 71 Bay Street, Toronto. (pfh)

WANTED—CHIEF DRAFTSMAN BY CONcern manufacturing very extensively sawmill and pulpmill machinery, boilers, engines, etc. Only those with suitable experience need apply. Apply, mentioning "Power House," to Waterous Engine Works Co., Limited, Brantford, Ontario. (pfh)

BOILERS, SMOKE STACKS, HOISTING ENgines, rock drills, grey iron castings. Apply, mentioning "Power House," to Napanee Iron Works, Ltd., Napanee. (pfh)

TWO GOLDIE-McCULLOCH H.R.T. BOILERS. 70 h.p., 60" diameter, 14" long; working pressure of 120 lbs.; complete. Apply, mentioning "Power House," to Wilson-McGovern, Ltd., 505-509 Lumsden Bldg., Toronto. (pfh)

POWER HOUSE

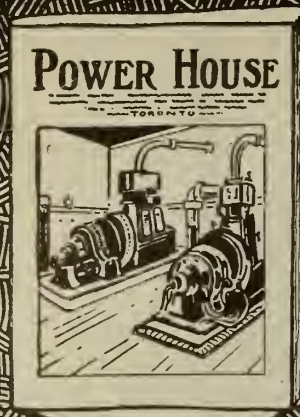
Solves the Problem

It is a dominating factor in maintaining power plant efficiency in equipment and service.

Every issue teems with advertising and editorial matter of a character that will keep YOU right up to the minute in power plant knowledge.

TWO ISSUES PER MONTH
TWENTY-FOUR PER YEAR

TWO DOLLARS



The Influential Four

For Self-Promotion and Sales Promotion Use These Publications

CANADIAN MACHINERY

Weekly—$4.00 per year.

Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

POWER HOUSE

Twice a month—$2.00 per year.

Serves the power plant engineer—Steam, Electric Refrigeration, Hydraulic.

CANADIAN FOUNDRYMAN

Monthly—$2.00 per year.

A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.

Interprets marine engineering in its broad sense, serving the ship builders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate).

Copes Boiler Feed Regulators
May All Look Alike,
but they work in many different ways

BEFORE a Copes Boiler Feed Regulator is installed, a careful study is made of the plant and its operating conditions. While the construction of the Copes is extremely simple, the essential parts are capable of many fine variations. They have been developed to meet every conceivable condition in boiler feed water regulation. No matter how difficult your problem, how futile and apparently hopeless all previous attempts at automatic boiler feed regulation may have been, we can provide a Copes that will handle it without fail.

Write for Bulletin D.

Could *you* retire in 20 years?

Perhaps you don't want to—but all the same it is a very pleasant feeling to have enough gilt-edged securities tucked away that if business does get troublesome you haven't the slightest worry.

A few days ago, there came to our office a merchant from a small Western Ontario town. Perhaps his business was not as big as it might have been, but he was pretty shrewd, for he knew that profit was profit only when you had it safely invested in gilt-edged securities.

For twenty years he had quietly invested his monthly profits, getting his information from the Investors' Enquiry Service of THE FINANCIAL POST. We had noticed his frequent letters, but we never knew just how he used them until he dropped in to see us.

Now his financial worries are over, having sold out and gone to live in sunny California. By following the Investors' Enquiry Service as a subscriber he quietly put away an investment that gave him a sure income sufficient to cover all his needs.

The big point is this—**profit is not profit until it is safely invested and bearing interest.** There is so much of the average merchant's earnings that is frittered away in non-essentials, when he might create an estate separate from his business load.

THE FINANCIAL POST points the way to safe, sane investments in sound securities. Through the Investors' Enquiry Service you get the bed-rock facts behind any and all investments. Before you buy—write.

The $5.00 invested in THE FINANCIAL POST service for a year will mean hundreds of dollars to you, if you follow the hints, tips and suggestions in the investment of your profits. When so many merchants have found its pages valuable to them, will you not fill in the coupon and find out for yourself just how valuable THE FINANCIAL POST can be to you?

THE FINANCIAL POST

143 University Avenue
TORONTO

THE FINANCIAL POST
143 University Ave.,
Toronto 1921

On the understanding that THE FINANCIAL POST contains just the facts I need for safe investment of profit, you may send me a recent issue.

Address .....

Sureness—

Should it come home to you—should your plant suffer an expensive breakdown, due to accumulated moisture in engine cylinders, wouldn't it pay to be sure?

Sureness means

THE ANDERSON
STEAM SEPARATOR

The Anderson Steam Separator is a positive protection against engine breakdowns because it delivers **dry steam** under all operating conditions. The moisture is completely separated by the combined action of centrifugal force and the sudden reversal of high velocity steam current—and the moisture cannot be picked up again when once separated.

Let us tell you more about the Anderson Separator, because it is one of the things you really need. A catalogue of this and other Anderson Power Plant Specialties will be forwarded on request.

The Anderson Separator should be in every boiler room.

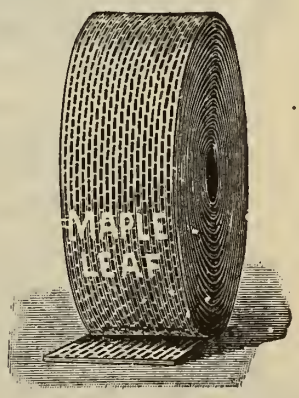
THE V. D. ANDERSON COMPANY
1935 West 95th St., CLEVELAND, OHIO

Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the Celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

AMBEST FLEXIBLE METALLIC PACKING

It does away entirely with the necessity of carrying a varied assortment of packings in stock, as from a single supply, in fact from the same can, you may pack anything, large or small.

For steam, water, oil, ammonia, air, low or high temperatures, superheated steam, turbines, etc.

It will stand service up to 600 degrees temperature, high speed and heavy pressure, without hardening, fusing, or softening, always remaining soft; cannot scratch, score or bind any rod, whether brass, iron, or steel.

Made from special non-friction metal in long, straight, pliable strands, carrying a superior mineral lubricant. It is easily separated and twisted into size needed.

Carried in Stock in Montreal.

SALES AGENTS:
Mill Supply Department

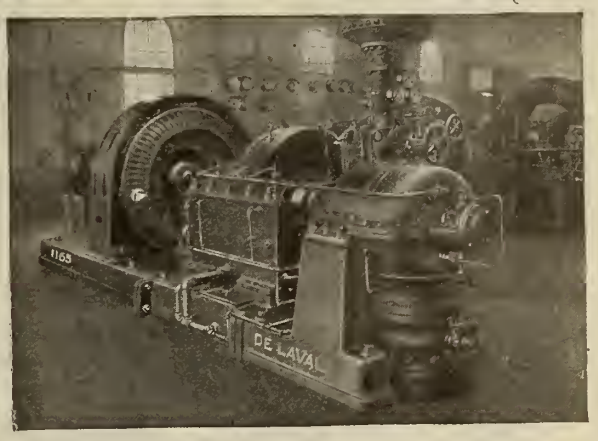
BEVERIDGE PAPER CO.
Limited
MONTREAL

SIMPLICITY vs. COMPLEXITY

THERE is no cheaper way of supplying power than to make it from steam which is to be used for heating or industrial purposes.

THE extraction of power from steam need not involve complicated and troublesome valve gears, pistons, packings, vibration, heavy foundations and all of the other undesirable features of reciprocating engines.

A TURBINE-DRIVEN A.C. or D.C. generator is more efficient, and is simple and easy to take care of.



350 K.W. Geared Turbine-driven Alternator.

IN a De Laval geared turbine driving a standard speed generator the only lubricating system is the self-contained and automatic one for the shaft bearings, which uses the same oil over and over. The exhaust steam is free from oil. As there is no vibration, only light foundations are required. All parts of the prime mover are easily accessible upon lifting the casing covers. About the only attention needed is the opening and closing of the throttle valve.

DE LAVAL Steam Turbines are made for all steam conditions, including high-pressure condensing and non-condensing, back pressure, mixed flow and bleeder services.

OUR engineers would be glad to make recommendations and to give estimates as to cost and performance. All De Laval apparatus is guaranteed as to efficiency and capacity and is tested before leaving our works.

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

One of the best illustrations that we can give of the effect of frictional heat is shown in the test of Magnolia Metal in comparison with a dozen or more of the best known brands of Genuine Babbitt.

This test was made by Dr. Torrey (deceased), then chief Assayer of the United States Mint at New York.

The Magnolia test block was run for eighty minutes with variable loads up to 2,000 pounds per square inch, 1,600 R. P. M. on 5-inch shaft.

Not one of the Genuine Babbitts came within measurable distance of Magnolia, as they ran out in from five to fifteen minutes at loads of 500 to 1,000 pounds per square inch—one reaching 1,400 pounds, but failing in ten minutes. The failure of the Genuine Babbitts was not from lack of quality, but simply because the frictional heat could not be prevented from reaching a destructive temperature, although tested on the same machine and under the same conditions as Magnolia.

Some of these genuines might have been slightly harder than Magnolia, and Magnolia would have squashed in exactly the same way under the same low stress, had not its self-lubricating quality kept the temperature from rising beyond a safe limit.

At moderate speeds and pressures these Genuines might never have given such evidence of their deficiency and would have been credited with being as good, if not better, than Magnolia.

This Magnolia quality, as exemplified by this test, shows the saving grace of a low frictional co-efficient and also the futility of mere hardness to save a metal from squashing.

(Continued next month).

ACT NOW!

You will be safe-guarded against boiler explosion due to low water, if you use VIGILANT REGULATORS. They cannot fail to operate and keep the water level where it will enable the boiler to produce the dryest steam at the highest economy figures.

The slow uniform feeding of these regulators means fuel economy, because the feed water is then heated uniformly to a higher degree.

Our instructive catalog will tell you more about the reason why the Vigilant will accomplish all that we claim for it, and more. Write.

MONCRIEFF'S "UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts.
It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Evaporators and Distillers.

Every Part is Interchangeable

A stoppage in the boiler room is an extremely serious matter. When, therefore, new equipment is required, prompt delivery and the interchangeability of parts is usually of vital importance.

As large stocks of standard Weir Products and parts are always carried in stock and in the course of constructing by us we are in an exceptionally favorable position to meet demands for urgent deliveries. Moreover, the well-known Weir system of interchangeable parts greatly facilitates overhauling and renewal.

This is but a single phase of Weir Service. To assist our customers in every way possible—to place at their disposal our entire organization—this is our aim.

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

What Single Investment Will Yield as Great Return as

Stoker-Firing?

Made in Canada For Canada

Jones stokers are the product of an old-established Canadian engineering organization, newly reorganized to render a greater service to Canadian power users. Jones stokers are made and sold by Canadians for Canadian money at par. The officers of the new company are prominent Canadian business men who have been leaders in the progress of Canadian industry. The reorganization also makes available for the new company, and for Canadian power users, the great engineering resources of the Under-Feed Stoker Company of America.

Jones

The Under-Feed Stoker Co. of Can

Canada's COAL WASTE?

STATISTICS show that one-seventh of the coal consumed by Canadian industries and public utilities is utterly wasted. Scientific combustion would have saved 1,000,000 tons of coal for Canadian power users last year; cut coal importation from ten millions to nine millions; released 20,000 coal cars for other service. There is no excuse for this waste for—

You Will Profit By Helping to End It!

Hundreds of Canadian plants have for many years recognized the great economy of stoker firing—but still are maintaining wasteful hand-fired plants. Why?

In some cases this is because their conception of stoker firing is based on the cost comparison of a few years back when coal and labor cost scarcely half as much as to-day. Stoker firing was merely a good investment then. But while coal and labor costs were soaring, the cost of a stoker installation has seen only a moderate increase. So to-day—

Can Any Equipment Prove as Great a Source of Profit as Stoker Firing?

In choosing a stoker remember that there is only one sound basis for your decision—a comparison of annual saving with first cost. The stoker that saves most will obviously cost least. Any stoker will save—but—

What Ordinary Stokers Do, Jones Stokers Do Better

They cost less by saving more—in installation cost; in maintenance cost, through greater simplicity; in fuel cost, through better application of the under-feed principle of combustion, originated in Jones Stokers; in labor costs, through automatic cleaning, automatic operation and many other outstanding advantages. They burn a wider range of cheaper fuel and meet every known load demand.

Don't you owe it to yourself and Canada to bring your ideas of stoker firing strictly up to date by reading the new Jones catalogs—or by availing yourself of the comprehensive service outlined on the opposite page?

HOW MUCH FUEL
IS SAVED BY
SUPERHEATED STEAM
That is the first question you naturally ask.
It may be only 10%, or it may be as high as 20%. One answer, however, is certain—the saving is always high enough to make the investment worth while. The less economical a plant is, the greater the saving possible by Superheating. "The ELESCO Superheater" is the answer to your second question of "How can I do it?" and is described in our Bulletins. Yours for the asking.
MORRIS

Republic

CO_2 RECORDERS

A Safe Guide to Fuel Economy

REPUBLIC CO_2 RECORDERS and FLOW METERS Make a Good Combination —*Use Both*

A colossal pile of fuel is wasted every year—over 150,000,000 tons in Canada and United States, it is estimated.

If you have no means of knowing whether you are manufacturing power economically or wastefully, you are probably contributing to this unnecessary waste. You can stop a great part of the loss in your plant by installing Republic CO_2 Recorders.

The Republic CO_2 Recorder has been developed to operate continuously under all boiler room conditions. This enables the operator to observe the conditions of combustion at all times and to obtain the highest efficiency from his furnace without fuel waste. MAY WE SEND YOU COMPLETE INFORMATION?

KELLOGG

A Name that Stands for the BEST in

CHIMNEYS

SECURING the **right** chimney for your plant is an important consideration. When you decide on a **Kellogg** you are safe! They have stood the test of time and have gained a world-wide reputation for reliability. The corrugated feature of **Kellogg** Radial Brick has proven a distinct advantage. The adhesion between mortar and **Kellogg** Corrugated Brick is 62½ per cent. greater than between mortar and ordinary straight or plain-sided brick; **Kellogg** construction is therefore safer and more endurable.

We can give you reliable advice on chimney construction—consult us before building your next chimney.

STEAM MORRISON GOODS

GRADE:

"Relative position or standing"
Daniel Webster

The "grade" of Morrison Steam Goods is "highest." Compare them with any other specialties; the service they render will prove their "relative position or standing."

"Every installation is a demonstration of merit"

The James Morrison Brass Mfg. Co., Limited

93-97 Adelaide St. West, Toronto

POWER HOUSE

A semi-monthly paper devoted to the Generation, Transmission, and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Avenue, Toronto

MONTREAL: Southam Building — LONDON, ENG.: 88 Fleet Street, E.C. — WINNIPEG: 1103 Union Trust Building

Vol. XIV.—No. 3. Publication Office, Toronto—February 5, 1921 — Published Semi-Monthly. Canada, $2; U.S. $2.50 a year

Uehling CO_2 Continuous Recording Equipment

HE LIKES UEHLING EQUIPMENT because it gives him, right in his office, a continuous record of the combustion efficiency of each individual boiler. It provides each day a twenty-four hour history of the fuel economy maintained and how much fuel is unnecessarily wasted up the chimney. The chart tells the results of each fireman's efforts and the condition of every boiler setting. Such daily information is a necessity if maximum economy is to be maintained.

HE IS PLEASED because the Cost of his Heat, Light and Power has been materially reduced. At almost every plant fuel represents one of the larger items of operating expense, but if the Chief Engineer is provided with UEHLING EQUIPMENT for keeping tabs on what is unnecessarily wasted, the large cash outlay for fuel can be reduced to a minimum. This is a fact proven by many repeated demonstrations.

The CO_2 Indicator at the Boiler enables the fireman to control the biggest waste of the boiler plant, just the same as the steam gauge makes it possible for him to control pressure. He knows what is indicated at the boiler front is being recorded in the office and he is happy because he knows he will get credit for his efforts in saving fuel.

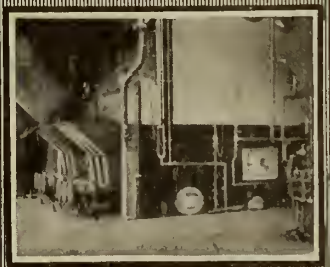
Combustion Engineers

2008 Empire Bldg. New York

Five Months of Steady Overloads
Boilers in this plant were kept on line continuously for five months at 150% to 250% of rating. Name on request.

Three Months Continuously—Peak Loads at 340%
Such is the operating record of this "A-C" equipped plant. Name furnished on request.



Three Months of High Capacity
Boilers kept on line continuously for over 3 months. Loads varied from 75% of boiler rating to 250%. Name on request.

THE HEAVY OVERLOAD CAPACITY
of the Jones "A-C" Stoker is
ALWAYS AVAILABLE

The modern plant demands a stoker that will deliver overratings *when wanted.*

Since the heavy overload capacity of the Jones "A-C" (Automatic-Cleaning) Stoker is not based on complications that could fail in the emergency, it can be depended upon to carry prolonged overloads and meet sudden demands for quick steam.

Here is a stoker that duplicates *"test runs"* in *daily service.* The records given opposite prove it! The rugged simplicity of the Jones "A-C" makes it just as good a producer in the hands of an ordinary operator as when manipulated by experts.

The sectional view above illustrates its extreme simplicity. Fuel is slowly moved through the extra long retorts by the pusher rod, which, with the simple ram and piston, constitute the *one* moving part. The pusher rod, the only moving part within the furnace, is buried deep in the green fuel, and is completely isolated from the hot coal.

Mechanically moved through the extra long retorts, fuel is completely volatilized and the released gases are thoroughly and smokelessly burned in the incandescent fuel bed. The slight slope of the retorts, preventing avalanching, and the complete combustion insure an absolute minimum of volatile in the ash when the dump plate is reached.

Individual control of retorts, absence of clinkers, and automatic control of fuel and air are features contributing to the heavy overload capacity of this high-duty stoker. These points of superiority are clearly explained in the new "A-C" catalog.

You have your copy?

100% CANADIAN

The Jones Under-Feed Stoker Company of Canada, a company with a record of a quarter of a century of success in the Canadian field, has been reorganized under the name of the Under-Feed Stoker Company of Canada, Ltd. The purpose of this reorganization is to place at the disposal of Canadian power users, not only the wealth of experience gained in the Canadian field, but also the broad engineering resources of the Under-Feed Stoker Co. of America.

81 Victoria Street, Toronto, Ont.

Jones "A-C"

BOILERS

FOR POWER AND HEATING PURPOSES

You will find Waterous Horizontal Return Tubular Boilers in the largest industrial and municipal power plants in the country. There are reasons for this. They are economical of fuel, carry a big reserve steam pressure for use in emergencies, can be used with hard and dirty water, and are readily cleaned and easily taken care of. They cost little new; their upkeep and maintenance expense is negligible.

Waterous Horizontal Return Tubular Boilers are built in all sizes from 40 inches by 10 feet to 72 inches by 18 feet. Most standard sizes are carried in stock. If we cannot supply you at once from our yards we can turn out your order for you in quick time. On the next boiler you need let us quote you prices and delivery.

Why Engineers Consult Worthington On Condenser Questions

THE largest and most important power plants in the United States—plants that have established and are holding records for economical power production are equipped with Worthington condensing apparatus.

Worthington was the pioneer in this branch of the power field, and for more than forty years has led the way in designing and constructing condensing apparatus of every type.

This accumulated experience enables Worthington to offer recommendations on condensing equipment to meet all conditions of service. The fact that Worthington builds all types of condensers guarantees impartial recommendations.

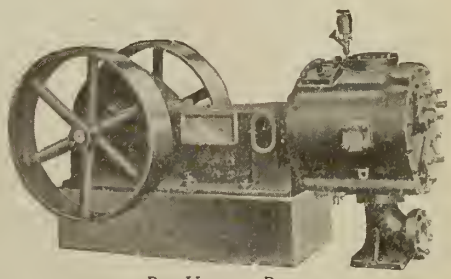
Duplex Packed Piston Pump



Dry Vacuum Pump

Surface Condenser

Worthington builds surface condensers of two general types — standard and the so-called waterworks type. Both are equally economical. They produce a net saving in the operation of the plant in which they are installed, sufficient to earn their first cost in a very short operating period. Working conditions determine the type of condenser to be used, and Worthington engineers make their recommendations accordingly.

BRASS GATE VALVES

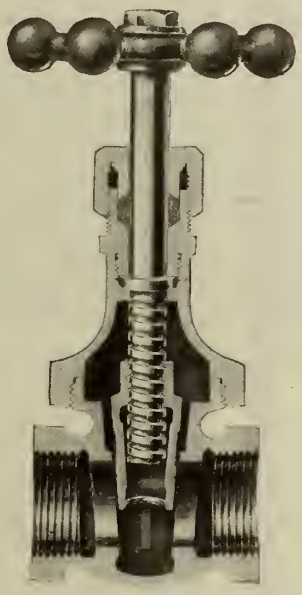

Fig. 567

"Outside Bonnet Construction"

Improved Design Improved Efficiency

All Penberthy Gate Valves are designed with outside bonnet construction, same as our compodisk and regrinding lines of valves. It is the most practical and reliable idea of valve construction.

Penberthy Gates are made with solid wedge disc, which has proven much superior to the split or two-piece disc type.

Penberthy Gates are Government registered for 150 lbs. steam pressure.

Design, workmanship and finish unequalled anywhere.

A strictly high-grade valve at a reasonable price. Specified by leading engineers.

PENBERTHY INJECTOR CO., LIMITED
WINDSOR CANADA

The Valve Value of the Century

These standard valves embody the following special features: (1) made of virgin metal, high in copper content, and of great density and steam resisting strength; (2) swivel disc spindle, bearing in center only; (3) extra long stuffing gland, giving the effect of a union bonnet; (4) large hexagon with ample clearance for wrench surface; (5) latest model barrel type body, exceptionally strong; (6) shut-off seat-valve can be repacked when open; (7) special packing of great steam resisting qualities — valves can be repacked under pressure.

Mueller Globe and Angle Valves

excel because of the above seven points of supremacy. They are competitive only in price. They lead in value and in dependable service.

Made in all sizes from ⅛" to 3" inclusive. Write for full description and prices. Mail orders given prompt attention.

SHEET PACKING
STYLE N°60
How Service provides for standardization
BECAUSE Service Sheet or gaskets cut from it will pack against steam, air, water, ammonia, oil and most chemical solutions successfully, it is possible to use it for all these conditions.
This makes standardization possible; means an elimination of several or many sheet packings; one sheet for all purposes; no mistakes in selecting the proper packing for a certain condition.
No large stock to eat up interest on investment; no perishable sheets; because Service Sheet lasts in stock as well as in joints. It does not rapidly deteriorate with age.
The standardization of sheet packing, or of all types of packings for that matter, means exactly the same as the standardization of anything—the elimination of the unnecessary and the use of the best.

EMPIRE

A-830

A name that stands for quality goods, always

FOR seventeen years the name EMPIRE has symbolized products made of highest-grade material, by careful workmen. Products that are carefully factory tested, guaranteed and that represent the best that money can buy. So it is with A-830, a Steam Valve which is tested to 175 pounds pressure. It's just one of the many hundreds of articles we make, yet it bears the name EMPIRE which is significant of its quality, workmanship, design and finish.

We make and supply all kinds of Sanitary Fixtures and Plumbing Supplies. If you need supplies, you need **EMPIRE SUPPLIES.** They are handled by leading jobbers throughout Canada. Write us.

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

New Truths and Old Fallacies

Hardness of Alloys

The foregoing brings us to the discussion of the relative hardness of White Metal Alloys.

Many babbitt users lay great stress upon obtaining extra hard metals; usually specifying tin base metals with high copper content. We shall submit, further on, some comparative figures which do not bear out the usually accepted belief in that connection, and are as subversive in their ways as are the figures relating to the melting points of metals. These figures do not sustain the reputation of copper as a hardener, nor of the superior hardness of tin base metals.

They also disclose the fact that if a babbitt's value depends upon its hardness, the lowest grades of babbitt would sustain the load put upon a majority of bearings, which rarely exceed 500 pounds per square inch, and often much less.

Extreme hardness can only be obtained at the expense of malleability. The hardest babbitt is a lead base metal containing a high percentage of antimony, which is quite brittle, and, therefore, its use is confined largely to Rolling Mill and other similar bearings where the lining is thick and securely backed to prevent the metal cracking.

Magnolia is often loosely characterized as being a soft metal. This is doubtlessly due to its velvety feeling to the touch, a less metallic ring than Genuine and its being easier to break. Not even the Brinell test is a safe guide in determining the relative resistance of babbitts under a crushing strain. In fact, there is a surprisingly small difference in the sustaining powers throughout the entire list of babbitts in general use.

Two Novel Plans for Harnessing Niagara

Two Schemes are Here Described, Original and Daring in Their Conception. One Suggests a Tunnel Through Goat Island, the Other a Gigantic Dam Below the Falls.

By T. KENNARD THOMSON

THE report on a new plan, or rather two new plans, for securing power from Niagara, which is here given, is the work of an engineer of Canadian birth and training.

Mr. T. Kennard Thomson enjoys the honor of being the first Bachelor of Science in engineering to graduate from the University of Toronto. Following his graduation he was with the C. P. R. on construction work, and later went to New York to practise as a consulting engineer.

One of his greatest achievements was the building of the foundations for the Singer Building on Broadway at that time the tallest building in the world. The fact that Mr. Thomson is a practical engineer, with a long and successful record in large undertakings, lends interest to the present scheme. The description of the plans in detail is given below.

Jan. 24, 1921.

To the Honorable Federal
Power Commission,
Washington, D. C.
Gentlemen:

We respectfully beg to submit that the greatest and most uniform and most needed water power resources in the world are in the Niagara River, and that we could obtain the maximum amount of power at the minimum of cost, from any further diversion of water from above the old Falls by our Goat Island plan, and that the best method of developing the maximum amount of power at the minimum of cost in the lower river is by an international dam at Foster's Flats, about 4 miles below the old falls.

While the Goat Island plan will be entirely within the United States, we believe that Canada would readily agree to an international development at that point, as it would obviously save money to the consumers on both sides of the line forever.

Our two projects do not interfere with any of the existing power companies in any way whatever.

Indeed, while we realize that the Governments should control the price for which the power will be sold, we realize the enterprise, the risk and capital which the five pioneer companies put into these original plants, and we therefore think that in fixing such prices, the pioneer companies should be allowed to charge a difference of say $10 a horsepower more than we do, if they so wish.

Neither Mr. Porter nor myself have any financial interest of any kind in any of the present companies.

We realize that no matter what power is sold for, it will always be worth what it cost to develop power by coal.

The cheapest power ever developed by coal in New York City before the war was by the New York Edison and New York Interborough, and it cost them an average of $32.19 a horsepower. That would be equivalent to $70 or $80 a horsepower in the State of New York now, and I was informed in December that it was then costing $90 a horsepower to develop by coal in the City of Toronto.

We can develop two million horsepower at our new dam at Foster's Flats, at a cost of less than $100,000,000 or $50 a horsepower, and can do nearly as well at Goat Island. That means that we could sell for less than $10 a horsepower.

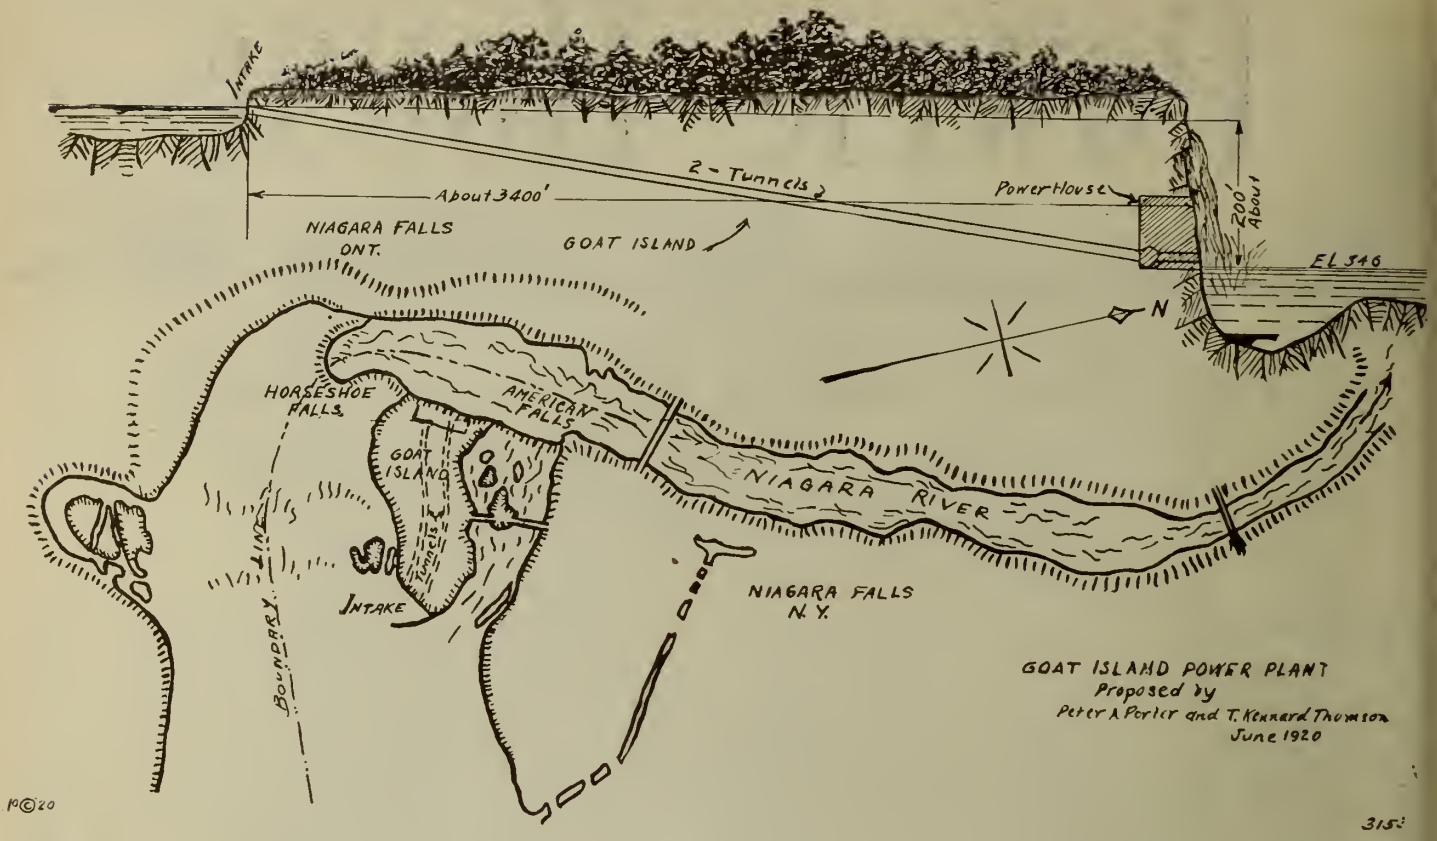
But, as there will never be enough water power to go around, if the manufacturers get our power at $10 or $15 a horsepower, they would have an unfair advantage over their competitors who had to pay $70 or $90 to develop power by coal.

The five pioneer companies developed 650,000 horsepower for $65,000,000 or $100 a horsepower. In doing this they attracted private capital to the extent of $650,000,000 or ten times what they spent themselves.

We claim, therefore, that it will be very much better to allow us to develop power and sell it for use within 100 miles from the site, thereby building up the greatest manufacturing district in the world, than to try to distribute it at long distances with scattering results.

When first I started nearly ten years ago to agitate for this dam, people laughed at the idea that there would ever be a demand for 2,000,000 horsepower. In 1917 I wrote to the director of census, Hon. Samuel W. Rogers, asking him how much power was then in use in the State of New York, and what the normal rate of increase was. He sent me a very comprehensive reply, which summed up that we were then using over 3,000,000 horsepower a year in New York State and that the normal rate of increase was 10 per cent. or 300,000 a year. In other words, half of our dam which would go to the States would only supply one-third the amount of power then being used in the State of New York alone, or would only supply the additional demand for the next three years.

On the other hand I might state that Niagara power is now being distributed in Syracuse, 160 miles away, with a loss of less than 10 per cent. using a voltage of 60,000. By increasing this voltage to 110,000 the power is distributed on the Canadian side of the Detroit River about 250 miles. By doubling this voltage again, making it 220,000, the distance of transmission could again be doubled, making it 500 miles, with the same loss. By examining the enclosed diagram showing circles around Niagara Falls of 100, 200, 300, 400, and 500 miles, which area includes part of nineteen states of the Union and two provinces of Canada and contains 60 per cent. of the entire population of the United States and 80 per cent. of the entire population of Canada, it will be seen that all of these would then be within commercial reach of this power, although, as we have shown above, we



would only have one-third the amount of power required by one state alone.

It might be stated that New York City alone uses between six and seven hundred thousand horsepower a year.

So the people on the frontier, especially in Canada, now realize that they want all the power that they can get developed.

Many people in Canada now realize that our proposed dam in Foster's Flats must be built sooner or later, and that when it is built, every cent spent on the Chippawa-Queenston Canal and similar diversions on either side of the River will have been so much money wasted, and I have not the slightest doubt that the Canadians will see the advisability of scrapping their canal, which I have been told is costing everywhere from $50,000,000 to $100,000,000 for the reason that no other plan or combination of plans will give within 1,000,000 horsepower as much as our dam will. And if Canada has half of that, it would be equivalent to 5,000,000 tons of coal a year at $10 a ton, making $50,000,000 a year. As soon as Canada is convinced, if she is not already convinced that she can get back the $50,000,000 a year, she will not hesitate to scrap the $100,000,000 plan if necessary.

As a matter of fact, however, it would not be necessary to scrap that or any of the other existing plants until they were worn out, but as our two projects are capable of using all the permissible water, such side issues simply add to the cost to the consumer forever. I have taken the liberty, Gentlemen, of going into such detail in the hope that you will not allow further partial developments on this side of the line, to thus add to the cost forever.

In addition, not only would such diversions greatly add to the cost forever, but, we are quite confident that any further diversion of water from the Rapids would result in an ice jam, which would probably destroy every plant in the River. My reason for this statement is that there is hardly enough water now going over the rocks in the Rapids to carry the ice away. As a proof of this statement; some dozen years ago, an ice jam was formed in the Rapids which only lasted eight hours, and kept the water back until it had done considerable damage to the power plants at the Falls, although such plants were at an elevation full 60 feet above the level of the water where the jam occurred, and when the jam broke, absolutely destroyed everything in the river below, all the way down to Lake Ontario for a height of over 20 or 30 feet above the original water level: wharfs, docks, trees, shrubs, buildings and everything being swept away. This jam was caused by a slight change in the wind at Buffalo, which held back the water for a short time, letting the ice pile up on the rocks in the Rapids.

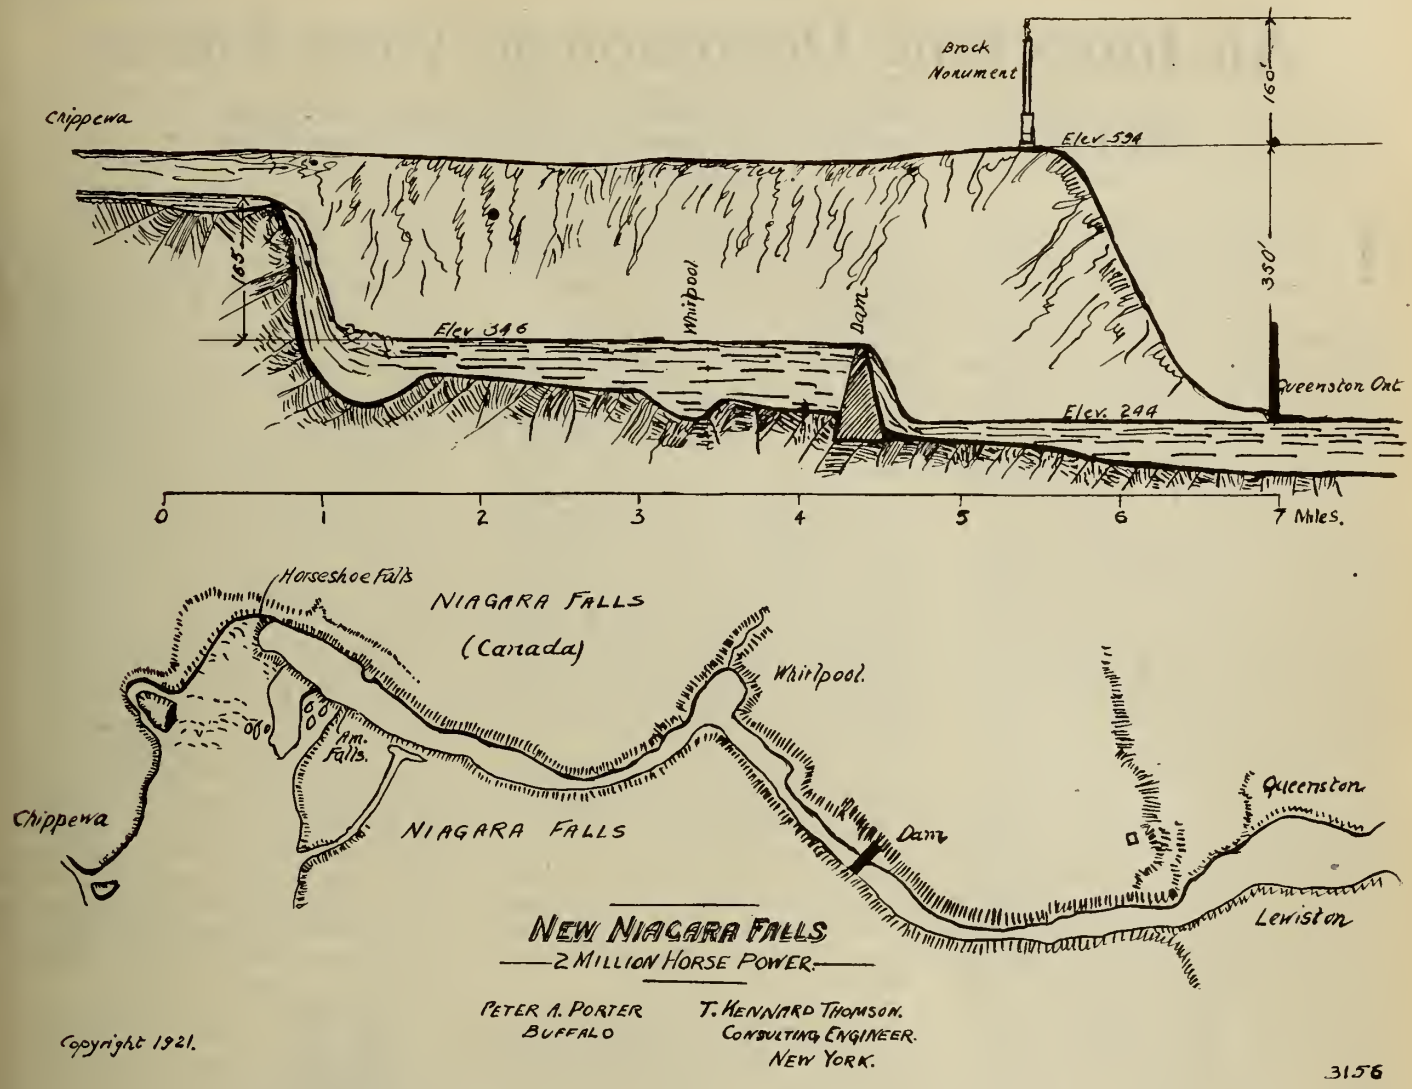
An engineer making as drastic a statement as this should give more than one example. So I go back probably some millions of years, when an ice jam probably diverted the Niagara River, causing it to turn a right angle thereby forming the whirlpool, cutting the brand new channel through the bed-rock.

By looking at the plan, it will be seen what an ideal location Foster's Flats is for the dam, for we can build the first part of the dam on dry land, carrying the base of the dam some 30 feet or more below the bed of the river and then divert the entire river through temporary openings at the bottom of the completed section of the dam, making it a comparatively simply matter then to dam the present channel of the river.

As we propose a dam with very flat slopes, about 700 feet base, it will be a very simple matter to handle the ice, as there will be nothing to prevent the ice from going right over the top of the dam, as there will be no sheer drop on the down stream side of the dam to undermine it, the ice simply sliding off on the flat incline. This design has been called a submerged weir. There will be a minimum depth of 135 feet above the dam and minimum flow of about 220,000 cubic feet per second, so there will be no obstruction arising from the ice.

Goat Island Plan

A glance at the plan will show an inclined tunnel of 2500 feet. It does not need any engineering figures to prove that such a tunnel is cheaper than tunnels five or six miles long or the Chippawa-Queenston Canal which is 12 3-4 miles long. Furthermore, we do not lose the valuable head which, in case of the Chippawa-Queenston Canal, amounts to 16 feet. This tunnel can of course be extended far enough above Goat Island to take advantage of the entire head of the river, at and just above, the old falls, and furthermore it does not de-



stroy any property or scenic beauty on Goat Island whatever.

These two projects together could develop about 4,000,000 horsepower a year, every ounce of which could be readily sold and it would be far better to sell it at the site, thereby developing great manufacturing centres and to pay enormous taxes to Canada and the States, so that all would derive equal benefits instead of taxing all for the benefit of a few.

At the same time the matter of canalization, and power, of the St. Lawrence River should also be started. While it is true that the bulk of the power of the St. Lawrence River belongs to Canada, the United States will benefit enormously by the canalization of the St. Lawrence River, as well indirectly from the development of the power.

For the development of 4,000,000 horsepower in the St. Lawrence River, and 4,000,000 horsepower in the Niagara River, or 8,000,000 horsepower together, or to be conservative say 6,000,000, which is equivalent to 6 million tons of coal a year, will mean that there will be ten Pittsburghs on the frontier. Such developments could not fail to benefit every town, village, and city in the United States and Canada. As a matter of fact, the United States will probably benefit by a 30-foot draft from Montreal to the Great Lakes to a much larger extent than Canada, as our country already has free use of the Canadian canals, and I have been informed often make more use of them than the Canadians. The profile will show that there are five lifts in the St. Lawrence River between Montreal and Lake Ontario, and these might possibly be cut down to 3 or 4.

If the United States and Canada will get together and give us the rights to develop this power, we will give a 30-foot draft to the Great Lakes without charge to either government, and we will develop power, under government supervision as to the plans, construction, operation, taxes, selling price of power and our remuneration.

If this work were done by government ownership in the old sense of the word, God help the countries! On the other hand, it will be inconceivable to give a private monopoly worth $600,000,000 or so a year to any individuals. But if the governments will give us the rights as above indicated, on the basis that we get so much remuneration if we develop power for say $15 a horsepower, less if it costs more than $15 a horsepower and much more for every dollar saved below $15, we would have all of the incentives of a private ownership without any of the objectionable features.

We therefore beg of you, Gentlemen, that you give us permission to develop the Goat Island plan, and that we also beg of you to arrange for an international agreement, treating the entire question as one unit, thereby saving untold millions to the future generations for they will undoubtedly have to pay not only for our two proposed projects in the future, but also for any and all of the minor diversions such as the Chippawa-Queenston Canal or tunnels on either side of the river.

We therefore respectfully state that we think you have it in your power to create the greatest industrial centres in the world, the results of which would be so far reaching that there is scarcely a country in the world that would not be benefited.

Respectfully submitted,

(Signd.) T. Kennard Thomson.

An Interesting Discussion on Valve Effects

The Effect of Various Valve Motions on the Compression and Mean Effective Pressure is Discussed, and a Rotary Type of Valve is Described

THE definite use of the superheater in order to improve the effectiveness of steam in locomotives is of comparatively recent date, having been introduced about 1900. According to Rafford, the idea of superheating steam originated with a mechanic, Francois Becker, who, in 1829, took out a patent for the first superheater on record. Three years later, in 1832, Trevithick took out an English patent for a vertical boiler with a superheater. The principle of construction of superheaters as they are now made is set forth in a patent issued to Quillacq and Monchenil, 1850, which showed the use of U tubes or similar elements placed in a series of fire tubes of large diameter, for the purpose of obtaining a superheat, and put into communication with collectors or headers, placed in the smoke box.

It has been the aim of builders for a long time to reduce the clearance space in the cylinder to a minimum. According to Nadal, the mere reduction of 30 per cent. in the surface of the clearance space, or from an area of five times to three and a half times the surface of the piston, will secure a saving of about 10 per cent. of the total steam consumption per horsepower hour; and, according to Ricour, the substitution of piston for flat valves on the State Railways of France decreased cylinder condensation by about one-quarter, when running with a cut-off at 30 per cent., with the consequent saving of 10 per cent. in steam consumption per horsepower hour as noted above.

The four-valve method of distribution, which forms the majority of improved valve gears, usually effects a wide opening for both the admission and exhaust valves, with a rapid closing of the former, thus avoiding wire drawing at short cut-offs. The steam passages are not bathed in exhaust steam, a fact which tends to reduce condensation on admission; the clearance space can also be made less than with the ordinary valve because of the short period of compression. These several considerations explain why the diagrams obtained with the four-valve method of distribution approach more nearly to the theoretical diagram than those of the ordinary method, and produce an increase of work and efficiency in comparison therewith. In fact, according to M. Nadal, the steam consumption per horsepower hour, on locomotives fitted with them, is 16 per cent less than with locomotives having the ordinary method of distribution, and their speeds on levels and slight grades (except in the case of motions using a dashpot, which do not work well at speeds above four revolutions per second) can be made to exceed the latter by from 3 to 6 miles per hour, other things being equal. This method of distribution is not, however, in extensive use, because of the complications involved.

The piston valves used, in 1882, on the State Railways of France, permit the reduction of the clearance space by the use of very short ports located at the ends of the cylinders. With the ordinary link motion, giving a long compression when the cut-off is short, it is impossible to take advantage of this to any great extent, and the volume of the clearance space ought not to be more than 5 or 6 per cent. of that of the cylinder, and the surface of this clearance space ought not to be more than 30 per cent. of that of locomotives having a plain flat valve, and this fact, as noted above, reduces the steam consumption per horsepower hour by 10 per cent.

With piston valves it is thus possible to make the compressions, to a certain extent, independent of the admission, and so to reduce it by giving the corresponding edge of the openings and the valve a helicoidal form, as well as by giving the valve stems a rotary movement, thus changing the lap and adapting it to the various running conditions.

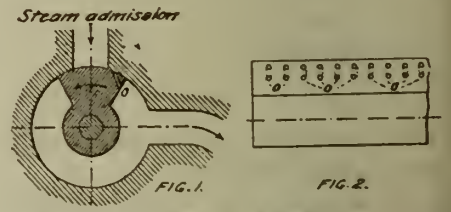
The reduction of the period of compression, on the other hand, depends on the volume of the clearance space, which should also be reduced as much as possible for the sake of steam efficiency; for even if it is filled by compression up to initial pressure, the work done by this steam represents a loss of about 30 per cent. of that done to compress it. If this volume is small, the work of compression will also be small, as well as the amount of condensation; but the final pressure of compression should not be greater than that of admission and it is this consideration which will determine its volume. On the other hand, this same pressure ought always to be sufficient, when joined with the pre-admission, to cause an arrest of the reciprocating parts without shock. The conclusion reached by M. Dwelshauvers-Dery, as a result of his investigations with different degrees of compression, is that operation without any compression would be most economical. We may cite the case of a Van den Kerchove-Bonjour condensing engine of the Corliss type in which an admission of wiredrawn steam is used during compression as shown in Figs. 1 and 2, by means of which the period of compression was reduced to 5 per cent with a clearance space of 5 per cent as shown in Fig. 3.

With the use of the Walschaerts gear, which has been generally applied to locomotives built during the past twenty years, the period of compression increases to an important extent as that of admission decreases, running from 10 per cent of the stroke with a cut-off at 70 per cent. to 42 per cent. when the point of cut-off falls to 10 per cent.

High speeds, at which the cut-off is short, thus still further increase the compression because the back pressure at the commencement of compression is still quite high, amounting to as much as 14 pounds per square inch for a speed of five revolutions per second.

If can be readily understood, that under these conditions a large clearance space is necessary with the link valve gear, and that it should be still more in the high pressure cylinder of compound locomotives where the back pressure at the end of the exhaust may be 25 pounds per square inch or more though the compression may be reduced to a period of 20 per cent. of the stroke. Still the clearance space should be at least 14 per cent of the cylinder volume.

By making the lap of the exhaust valves variable, by the use of a helical form and the rotation of the valve stem, it is possible to reduce the period of compression very materially, and, with



1. CROSS SECTION OF ADMISSION VALVE FITTED WITH OPENINGS FOR PRE-ADMISSION.
2. PLAN OF SAME VALVE.

it, the pressure at the end of the same as well as the clearance space, thus providing for a shorter cut-off while running. It is possible to use a considerable negative exhaust lap when running in this way. But with narrow ports and flat valves such a negative lap presents certain disadvantages, because when at mid stroke or near it, such a valve puts the two ends of the cylinder into communication with each other; so that the steam working expansively at a high pressure on one side of the piston would lose a part of that pressure in passing to the other side, where exhaust is taking place, the pressure of which will be raised by this inflow, causing a second loss of motor work. At high piston speeds corresponding to cut-offs this disadvantage is greatly reduced, even with flat valves, and disappears almost entirely when piston valves, set at the ends of the cylinders, are used with an outside exhaust into separate ports which only come together at some distance from the open-

ing, as is the case, for example, in the compound locomotives with piston valves of the Eastern Railway.

A negative lap of 0.4 inch can be given to the exhaust side of piston valves for high speed running. For full stroke, at the moment of starting, it would be advantageous, on the other hand, to use a lap of 0.2 inch. There is thus a total variation of 0.6 inch which could be made between running at 75 per cent. and 15 per cent. cut-off, so that for each ten per cent. of reduction of cut-off a corresponding reduction of 0.1 inch could be made in the inside lap.

If the actual satisfactory cut-off should be taken as lying between 35 per cent. and full stroke, the limit of variations of the inside lap should be taken between cut-offs of 35 and 15 per cent.

Finally, changes in lap could be obtained by the movement of a second valve placed under the control of the engineer; an arrangement possessed of several advantages for preliminary tests, or automatically, as shown in Fig. 4, which requires no particular attention on the part of the engineer, and when in operation involves no moving parts.

Without being of the same importance, a certain amount of variation in admission lap would also be an advantage. We know that with the Walschaerts and Gooch valve gears there is a constant lead which is not always a logical arrangement. In the United States it is generally considered that, when running with a full stroke cut-off, at starting or at slow speeds, there should be no lead because at the commencement of admission the steam chest pressure would be at once established in the cylinders and that a lead, however short, would be of no advantage and would set up a resistance that would reduce the motive power.

At high speeds, on the other hand, a certain amount of lead is considered necessary in order to fill the clearance spaces with steam at boiler pressure at the commencement of the stroke, and thus obtain a supplementary opening of the ports without which, at short cut-offs and at these speeds, a considerable amount of wire drawing would occur, thus causing a reduction of the average pressure, which would be detrimental to the efficiency and power development of the engine. From this standpoint, then, the lead could be advantageously varied from 0.04 inch or nothing for a full-stroke cut-off, to 0.16 inch or even .25 inch when the cut-off takes place at from 12 per cent. to 15 per cent. of the stroke. A helical outline of the lip of the valve, given a rotary movement when a change of cut-off is made, would make the desired change of lead automatically.

Finally, it is possible to obtain for all points of cut-off, a difficult pre-exhaust and compression lap of the valves (producing, for example, a later exhaust opening and closure at once, while effecting a wider port opening at the same time), by giving the valves a helical movement, resulting from their regular longitudinal movement and a complementary rotation, produced by an articulated crank attached, at one end, to the lower portion of the lap-and-lead lever of the Walschaerts gear, and, at the other, to a small lever mounted on the valve stem.

With the different arrangements indicated above, the rotation of the valves would improve the lubrication and reduce the wear by regulating it.

M. Desdoints, former superintendent of motive power of the State Railways of France, in a study of the power and resistances developed in hauling trains, very clearly set forth the advantages of an exhaust lap that was variable with the speed and, consequently, with the point of cut-off.

"A reduction of the exhaust lap," he said, "has the effect of lowering the curve of motor effect at low speeds and raising it at high speeds." So that the best results for the different speeds of a run will be obtained by using a different lap for each of them, which can be readily obtained by the use of the hand arrangement indicated above. M. Desdoints added, apropos of the lowered efficiency of locomotives at high speeds: "A proper reduction of the exhaust lap ought to have the effect of greatly reducing, if not

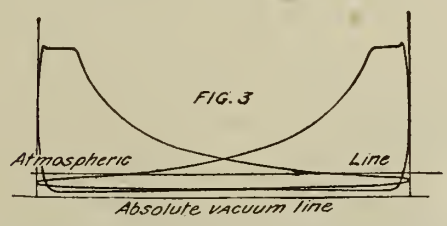


DIAGRAM OF A 300 H.P. CORLISS ENGINE FITTED WITH SPECIAL VALVE SHEWN IN 1 AND 2.

entirely doing away with the lowered efficiency, at high speeds." Finally, in speaking of possible running speeds, he said: "A representative diagram of the tractive effort developed for different points of cut-off, according to the running speed, will make it possible to determine the maximum speeds attainable on a given profile, for a train whose resistance is known: the intersection of the line of this resistance with the curve of tractive effort will give the speed sought. For a given engine it would be impossible to obtain more than belonged to the production of the boiler; but a reduction of the exhaust lap, causing an elevation of the curve of mean effective pressure, should raise the limit of possible speeds."

The use of admission valves with a variable lap would then be a logical thing to use and would secure, at the same time, an increase of efficiency and an improvement in mechanical action. As the superheated steam at high pressure, owing to its high speed of flow, permits the use of short cut-offs of from 12 to 15 per cent. and renders the reduction of compression possible, so that compounding can be dispensed with and simple expansion is thoroughly justified; a point the desirability of which is conceded by all engineers.

The improved methods of distribution with saturated steam will be as economical as compound operation with a flat valve. The advantages and disadvantages of compound operation taken from a comparison of the consumption of sensible and condensed steam in a compound and a single expansion engine, have been set forth by Mr. Vadal, as follows:

The ratio of expansion is usually higher in the first than in the second, except when the latter is fitted with a four-valve distribution, or generally speaking as the comparison is reduced, and this is a benefit, but, on the other hand, there is a loss of area in the compound diagrams because of the transference of the steam, through the receiver, from the high to the low pressure cylinder, and the fall in pressure, which increases with the speed that results. If we look at a totalized diagram of a compound engine, we will see that the admission line of the low pressure cylinder is very much below the exhaust line of the high pressure cylinder, and that a considerable area is thus lost, a loss that has no equivalent in a single expansion engine. This loss, due to transference, is much greater than the advantage obtained by the increase of expansion and results in a greater consumption of sensible steam per indicated horsepower in the compound engine. For example, at a pressure of about 170 lbs. per sq. in. with the cut-off ranging from 10 to 20 per cent. of the stroke, the ordinary locomotive uses from 12.5 to 16 lbs. of sensible steam per indicated horsepower hour, while the compound, between 30 and 50 horsepower, uses from 15 to 17.5 lbs., an increase of about 1.5 lbs. per horsepower hour. At a ruling pressure of 210 lbs. per sq. in. this increase is only about 1.4 lbs. It, therefore, increases as the pressure decreases.

On the other hand, in the compound system, where the expansion is divided between the two cylinders, the amount of steam condensed per horsepower hour is notably less, that is, it is about one-half because it is proportional to the variation in temperature in the high pressure cylinder. The actual advantage of the compound system lies in the difference between the lessening of condensation and the increase in the use of sensible steam. It can readily be seen that this difference may not always be a positive quantity. It may, in fact, be negative if the ruling pressure is too low, that is to say, below 140 lbs. per sq. in., provided the speed of rotation, at the same time, is less than three revolutions per second.

But, for high pressures, there is a positive net gain. For the same average pressure, under ordinary running conditions, compounding effects a saving of from 5 to 6 per cent. with a pressure of 170 lbs. per sq. in. If the pressure is raised to 210 lbs. the saving will be from 8 to 9 per cent.

In locomotives having four valves, as

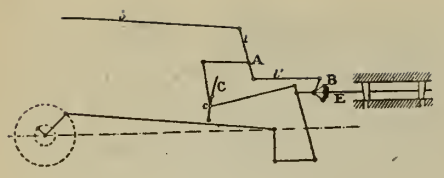

FIG. 4.

General view of valve gear designed by the author having a piston valve with a lap varying with cut off. A, lifting shaft. B, toothed sector for rotating the valve stem. C, link. b, reach rod. c, link block. L, lifting shaft lever. L1, reach rod for rotating valve stem.

great a ratio of expansion can be used as in the compound without having, as in the latter, any special loss in the amount of sensible steam used. But the losses by condensation can only be reduced by reducing the area of the clearance space and the period of compression, which is the essential characteristic of the improved method of distribution. The saving effected in comparison with a single expansion locomotive using a plain flat valve is almost as great as that obtained by compounding.

These conclusions are based upon the result of tests made in service on the State Railway of France on high speed trains, with a State locomotive having piston valves and a Ricour valve gear working under a pressure of 200 lbs. per sq. in. and a four-cylinder compound Midi locomotive using the same steam pressure. The boilers of the two engines were of the same power and they had practically the same weight on their axles. In summing up the matter, Mr. Desdouits says:

"For ordinary express service, the two types of engines develop the same amount of power, but the single expansion locomotive is the more economical of the two.

"For high speed and extra high speed, that is, for trains running at a speed of 62 miles an hour, the single expansion machine holds its own in work done and economy in operation.

"For exceptional work on steep grades or where the weight of the trains is up to the available tractive effort, the compound locomotive will develop more power and will have a lower steam consumption than a similar single expansion engine. But with suitable diameters of drivers the single expansion engine will hold its own."

In the above tests the water consumption of the locomotives having the Ricour gear dropped to 18.6 lbs. per horsepower hour, with a coal consumption of 2.4 lbs., confirming, as Mr. Desdouits says, the efficiency of these engines when working a fast schedule and making from four to five revolutions per minute.

By permitting a reduction of the area of the clearance space, together with a reduction of the period of compression, the use of piston valves having an inside and outside lap that is variable with the point of cut-off, the thermic and mechanical efficiency of these locomotives can be still further improved. Finally with super-heated steam, which is favorable to the use of the short cut-offs that are possible with high pressures, a most satisfactory general efficiency can be obtained with a valve mechanism quite as simple as that used in the compound system. —L. Pierre-Guedon in Le Genie Civil.

AUTOMATIC LIGHT AND POWER STATION

There has recently been placed in operation by the St. Paul (Minnesota) Gas Light Co. an automatic substation supplying power to the Edison three-wire distribution system. The equipment in this station, which is of Westinghouse manufacture, consists of a 500 KW, 250-125 volt direct-current compound, commutating pole, compensated generator directly connected to a 4,000 volt, three phase, 60 cycle, 1,200 r.p.m. synchronous motor, together with complete automatic switching equipment.

This substation is located in the subbasement of the new Hamm Building, which houses the large new and beautifully modern Capitol Theatre devoted to the cinema art. Also in addition to many shops and floors of offices, there is operating in the first basement the St. Paul Amusement Co., devoted to bowling and billiards.

To supply this establishment with service from the light company's network, it would require not only additions to the capacity of an existing substation, but the addition of copper to the distributing network as well. In the nearest substation no space is available for the installation of an additional unit. The automatic substation, designed to give to this building a preferred service, solves the problem. During periods of light load, the substation is idle, the building being supplied from the Edison voltage below a predetermined value, the equipment receiving a starting impulse from a contact-making voltmeter, puts the substation into service. Operation of the station is continued until the load drops below a predetermined value and remains at or below this value for a given length of time, when the station is cut out of action by the action of a small motor operated timing relay. The system direct-current voltage is now above the setting of the contact-making voltmeter, so that the station remains idle until the dropping network voltage indicates further demand.

While the substation is in operation, it is paralleled with the network until the current to it is in excess of one-half the capacity of the machine, when a small amount of resistance is cut into series with the feeder, thus dropping the voltage to effect a dropping of load. This is accomplished by the functioning of direct-current, reverse current relays controlling the operation of the electrically operated contactor switches. When the substation is idle, the current inflow to the building from the network is not limited. It is thus seen that this building receives a preferred service. An outage on the direct-current network leaves the building to be supplied from the substation. Conversely, an outage of the substation leaves the building to be supplied from the network. This combination thus establishes very good voltage regulation of the service supplied to this location.

Protective features similar to those supplied for railway automatic substations and other features peculiar to this type of equipment afford complete protection to the apparatus. The success of this equipment as shown by the initial operation is already assured. It demonstrates a new application of automatic switching which opens the way to perhaps even a greater field than any that has so far been entered with this class of apparatus.

NONCONDENSABLE GASES IN REFRIGERATION MACHINES

(Abstract of Technologic Paper of the Bureau of Standards No. 180, by E. C. McKelvy and Aaron Isaacs.)

In the experiments conducted at the Bureau of Standards the conditions existing during the operation of an ammonia absorption refrigeration machine were duplicated. It was found that the presence of the noncondensable gases that cause so much trouble in the operation of these plants is due to either or both of these causes: (1) Leaks of air into the system, and (2) the corrosive action of the aqua ammonia on the metal of the plant.

If the "foul" gas is mainly nitrogen, the gas is derived from air that is leaking into the system. The oxygen originally present in the air is quickly used up when the plant is operating and so will be present in only a very small percentage of its original amount. If the foul gas is hydrogen, the cause is corrosion by the ammonia liquor. Pure aqua ammonia will not cause gas formation; but if salts of such weak acids as acetic or carbonic acid are present in the "aqua," the corrosive action will continue during the life of the charge. If the gas contains both nitrogen and hydrogen, both causes are present.

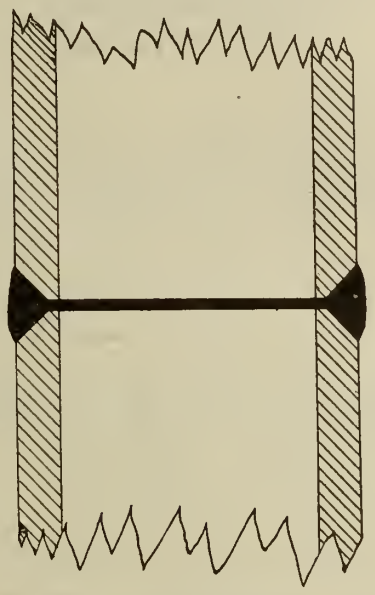
The corrosive action of impure aqua may be completely stopped by the addition of either sodium or potassium dichromate to the aqua in the plant. The dichromate is conveniently added in the form of a concentrated solution, and gas formation will be stopped if the salt is added to the extent of 0.2 per cent. of the weight of the aqua present.

The Hanson Clutch & Machinery Co., Tiffin, Ohio, announce that their new General Catalogue C-3 is completed and now ready for distribution. This booklet will be a handy reference for anyone using or contemplating using friction clutches, as it is complete in every detail. Hanson friction clutches meet a very large range of power and transmission problems.

A Steam Pipe that is Over 1,000 Feet Long

An interesting job in oxy-acetylene welding is being carried out in connection with the installation of the heating plant for the Toronto Union Station. The steam pipes are being brought from the steam power plant of the Toronto & Niagara Power Co., which is distant from the station about one-quarter of a mile, and the joints are all being made by the welding process.

Two pipes are being installed, one eight inch diameter and one four-inch diameter, the larger one being for winter use, and the smaller for the summer months. They are both high pressure lines, being designed for a pressure of 200 pounds per square inch. They are being laid in an eight feet deep trench, the pipes being carried on rollers, which are laid in brackets on a concrete foundation. Expansion joints are installed at about every 200 feet. When completed, the trench will be filled in, the only access being left at the expansion joints, where a manhole will be left at each one, for inspection purposes.



SECTION OF PIPE SHEWING WELD

Owing to the size of the pipes, they have to be welded in place, and this of course necessitates that half of each weld has to be made from the bottom side, or in other words, is an overhead weld. Needless to say, to perform this properly calls for considerable skill on the part of the operator.

In order to facilitate the welding the pipes were chamfered at the mill, and the cut shows very clearly this chamfering. During the welding the pipes are left one-eighth of an inch apart, to insure a solid weld being obtained.

The success of this job will no doubt give an impetus to the welding of underground steam pipes, as being a permanent job, with no chance of gaskets blowing out. The work is being performed by the Carter Welding Co., of Toronto, who are well known in this line of work. The work is being performed to the satisfaction of the Ontario Boiler Inspection Department.

A VIEW OF THE WELDING OPERATION

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

BEFORE proceeding further with the study of the indicator card, in its relation to the distribution of steam, it is advisable to look into the action of the apparatus which controls that distribution. We can then better understand what we shall learn from the indicator card.

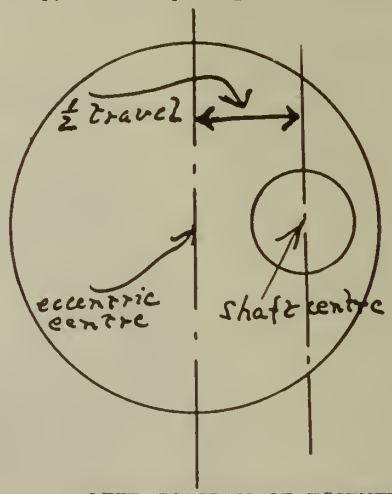
Steam distribution in an engine cylinder is affected by the use of valves, either sliding or rotary, operated by the motion of the engine itself. The valve most generally in use is the slide valve, in its various forms, with the semi-rotary valve of the Corliss type probably second, gridiron type slide valves like the Wheelock or MacIntosh Seymour being in fairly wide use, and poppet valves of the Brown type also having many users. Some of the leading Continental makers use the poppet type of valve, in conjunction with superheated steam. The Uni-Flow type of engine uses a poppet valve. These different types of steam distribution valves are actuated either by an eccentric on the crank shaft, or by means of cams mounted on a shaft which is driven by bevel gearing from the crank shaft. The motion is always derived from the engine itself, in some types being actuated by rods without the interposition of an eccentric or cam shaft, these gears being known as radial gears. The locomotive type of valve gear is a noticeable example of these latter gears.

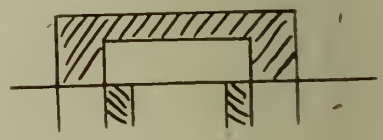
In the vast majority of stationary engines the eccentric is in use, and once having a good knowledge of the action of a slide valve operated by the usual eccentric, it is easier to follow the other types of gears.

The Eccentric and Slide Valve

In the early steam engines of Watt, it was necessary for a boy to stand at a lever and move the steam valve backward and forward to keep the engine in motion. It is to one of these boys that the invention of the eccentric is credited. Being like most boys, inclined to play rather than work, and finding his job somewhat monotonous, he cast about for a means of relieving himself of some of it. He suddenly hit upon the idea of attaching a rope to the end of his lever, attaching the other end to a moving part of the engine in such a way that it gave the desired motion to the valve. It was from this that the eccentric was developed. The eccentric is simply a form of crank, but it has the advantage that it can be put on the shaft at any portion of the length, can be made in halves if necessary, and can be turned round on the shaft to any position independent of the connecting rod or eccentric rod which it works. It is called an eccentric because its centre is eccentric to the centre of the crank shaft, instead of concentric, and it is the amount of this eccentricity, or the distance from the centre of shaft to the centre of eccentric that determines the travel or stroke of the eccentric. The diameter of the eccentric sheave or pulley itself has no bearing on the length of its travel. The distance from the centre of shaft to centre of eccentric corresponds exactly to the distance from the centre of shaft to the centre of crank pin in an ordinary crank. The illustrations herewith make this clear.

If we now place around this eccentric a ring or strap, which is able to slide, or allow the sheave to slide around inside it and let the eccentric be keyed to the shaft, while the strap is held at one point; if the shaft be now revolved, the eccentric will give a reciprocating motion to the strap, and to the rod fastened to the strap, thus completing the similarity





LEFT—DIAGRAM OF ECCENTRIC. RIGHT—VALVE WITHOUT CAP

to the ordinary crank and connecting rod. The eccentric pulley or sheave is the crank pin, the strap and rod form the connecting rod and crank pin bearing, while the valve spindle takes the place of the piston rod. Thus while the crank and connecting rod are changing the reciprocating motion of the piston into the circular motion of the crankshaft, the eccentric sheave strap and rod are changing the circular motion back again to the reciprocating motion of the slide valve, which is controlling the distribution of steam to the piston.

The steam distributing valve or slide valve we are now considering has to perform the functions for each end of the cylinder in a double acting cylinder, and these functions are four at each end. It must control the admission, cut-off, release, and compression of the steam during the outward and inward stroke at each side of the piston. As the steam is exhausted from behind the piston through the same passage as it is admitted by, at each end, the problem was to keep the cylinder alternately in connection with live steam and the atmosphere or condenser, and in order to do this the slide valve was evolved.

The slide valve in its simplest form consists of two flat plates joined together by an arch, the spring of the arch forming a cavity for the escape of steam, and the flat plates forming the means of opening and closing the passages to the cylinder as they moved across them. The only difference in slide valves is that in the larger ones in order to get a good port opening with small travel, they are made double and sometimes triple ported. These will be explained later, as will the piston valve, which is only a modified form of slide valve.

As we now have seen the means empoyed for moving the slide valve, and have an idea of the functions of that valve, we can go ahead and find out some more about it.

The steam chest face has three openings into it, one at each side leading to opposite ends of the cylinder, and the centre one communicating with the exhaust passage. The simple form of slide valve would have to be of sufficient width to just cover these openings when in its middle position. It would then have to have enough travel to move far enough on each side of the centre line to uncover the ports first to steam and then to exhaust, or in other words, to put the cylinder first in communication with the steam chest, and then with the exhaust

passage. From this we see that the amount of travel that would have to be given to the valve would be equal to twice the port opening. Then the stroke of the eccentric would be two port openings, and the amount of eccentricity, or distance from centre of shaft to centre of eccentric would be equal to one port opening.

Now in order to admit the steam to the cylinder at the proper moment the valve must be in a definite position in relation to the piston, and the eccentric must be in a definite position in relation to the crank. What must those positions be? A little thought will soon show that when the piston is just beginning its stroke, the valve must be just on the point of opening the passage to steam. Now when the valve is in its mid position it is just covering the ports. Therefore we must have the valve at midstroke just as the piston is at the beginning of the stroke. That means that the crank which drives the valve, or the eccentric, must be at its mid position when the engine crank is at the beginning of its stroke. As the full stroke of the crank sweeps through 180 degrees, the eccentric must be half that number of degrees in advance of the crank, or 90 degrees. Thus we have the position of the eccentric for a simple slide valve having no lap or lead. In a valve of this kind steam will be carried the whole length of the stroke. This is not conducive to economical working, so that in order to get an earlier cutoff the valve must be modified somewhat.

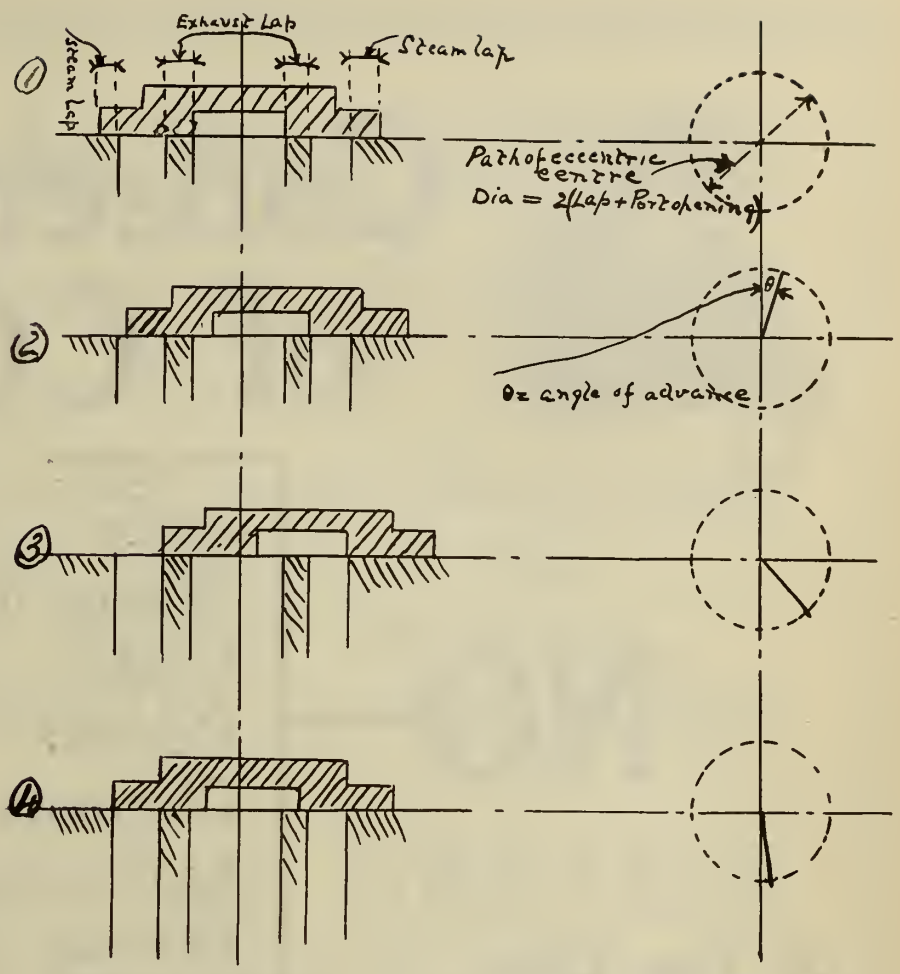


DIAGRAM SHOWING POSITION OF VALVE AND ECCENTRIC THROUGHOUT STROKE.

Steam Lap

Looking at our simple valve it becomes evident that the outside edge of the valve at each end governs the admission and cutoff of steam, while the inside edge effects the release to exhaust and the closing to exhaust. We therefore see that if we wish to have the cutoff take place at any time less than full stroke we have got to do something with the edge of the slide valve that governs the steam supply. What we want to do is to have the steam admitted at approximately the same time, but we want to effect the cutoff at say about three-quarter stroke. That means that our valve must start to travel backwards earlier than it did so as to cover the steam port when the piston is at three-quarter stroke. But another difficulty arises if we succeed in that. The exhaust port will be opened at practically the same time and thus there will be no benefit from the expansion of steam, and we will merely have less work without any economy.

In order to get over these difficulties, the faces of the valve are made longer, so that they project over the ports a certain amount when the valve is in mid position. The amount that they project beyond the outside edge of the port is known as the steam lap, while the amount on the inside is known as exhaust lap. Now the immediate result of putting this lap on the valve is that when the piston is at the beginning of its stroke, the eccentric being 90 degrees ahead of the crank, the valve will not be in position to open to steam. Obviously, we must bring it into position by turning the eccentric still further ahead of the crank, an amount sufficient to bring the edge of the valve to the edge of the port. It is usual to bring the edge of the valve a little bit past the edge of the port so that when the piston is starting its stroke the valve has already opened a certain amount, and this amount is called the lead of the valve. Thus we have moved the eccentric from its original position at 90 degrees ahead of the crank to a position as much further ahead as the combined amount of the lap and lead of the valve. This further angle we have moved the eccentric through is known as the angle of advance. Thus the total amount an eccentric is placed ahead of the crank will be 90 degrees plus the angle of advance.

Having gone this far, we are now in a

DIAGRAM SHOWING VALVE AND ECCENTRIC POSITIONS THROUGHOUT STROKE.

position to follow the valve through a complete revolution of the crank shaft, and observe the performance of the different functions. We can also draw a card to correspond to the various points of steam distribution and thus get a very clear idea of the valve motion and its effect on the diagram.

Starting with the piston at the beginning of its stroke, and the valve open the amount of the lead, the piston moves out, and the valve moves in the same direction until the port is open the full amount, when the eccentric is at the extreme point of its travel. The valve then moves in a direction opposite to the motion of the piston until the outside edge of the valve covers the steam port, when cutoff takes place. The piston continues to move outwards, and the valve inwards, until the inside edge of the valve uncovers the inside edge of the port, when release takes place. The piston moves on a little way further to the end of its stroke, the valve still moving the opposite way until the exhaust opening is at its maximum. The piston by this time has reversed its motion, and the valve starts on its return, covering the exhaust edge of the port and effecting compression while the piston is still moving inwards. When the piston is not quite at the end of its return stroke, the valve has moved forward far enough to uncover the steam port, until when the piston is at its extreme travel, the valve is again open to lead, and the revolution is complete. The same action takes place on the other side of the piston, so that by following the movement on one side, we get all the necessary information.

The amount of exhaust lap as shown in the diagrams is rather more than would be the case in practice, but the sketches do not pretend to accuracy, but are merely for the purpose of following the motion of the valve throughout a stroke. The proper proportions of valve can be determined by means of a diagram, which we shall explain in due course.

The foregoing allows us to make some definitions which are easy to remember, and important enough to be worth remembering.

Eccentricity=Distance from centre of shaft to centre of eccentric.

Travel of Eccentric=Twice the eccentricity=2(Lap plus Lead).

Steam Lap=Amount valve projects over outside edge of port when in mid position.

Exhaust Lap=Amount valve projects over inner edge of port when in mid position.

Lead=Amount valve is open to steam when piston is at beginning of stroke.

The four cardinal points of the valve function are Admission, Cutoff, Release, and Compression. The first two are controlled by the outside edge of the valve and the latter two by the inside edges. We will consider the setting of various forms of valves and the effect of wrong setting on the indicator cards, also the determination of clearance by the card, etc., in subsequent lessons.

Catalogues

Announcement is made by the Atlas Valve Co., Newark, N.J., that in rounding out their line of high grade valves—reducing valves, pump governors, pressure regulators, hot water regulators, control valves, damper regulators, etc.—they have now added the "Ideal" automatic pump governor, having acquired sole patents and rights to manufacture by purchasing from the Ideal Automatic Manufacturing Co. This pump governor has been approved by the United States Navy and by National Board of Supervising Inspectors of Steam Vessels for controlling certain exacting operations.

"Ideal" automatic governors are constructed either to maintain a constant pressure or to permit of variation of the pressure as desired. They are used for controlling automatic fire sprinkling system pumps, elevator pumps, turbine step-bearing pumps, hydraulic pumps, ammonia, gas and air compressors, and any other apparatus requiring sensitive reliable automatic pressure control of steam, water or pneumatic power.

We have received a bulletin describing the Yarway-Lea V-Notch meter, made by the Yarnall Waring Co., Philadelphia. This meter is adapted for use as a boiler feed water meter, and it is claimed that it is accurate to within 1½ per cent. of the actual weight of the water with any variation of temperature or flow. The meter in general design consists of a cast iron casing, which contains two chambers, the top one containing the V notch and the lower one being used as a storage chamber. There is a float in the lower chamber, operating a balanced valve, which controls the admission of water to the upper chamber, thus ensuring a regulated flow to the notch. The recording mechanism provides four kinds of information: Inches of head falling over weir, instanteous indication of rate of flow, graphic record in pounds or gallons during any part of twenty-four hours, or total weight of water between any two readings.

We have received the new catalogue of the Coppus Turbo Blower, manufactured by the Coppus Engineering and Equipment Co., Worcester, Mass. The new booklet gives some interesting comparisons between forced and induced draft, and then gives a clear and well illustrated description of the Coppus blower. The various parts are shown in detail, and some illustrations of plants are included where installations have been made.

TRADE ANNOUNCEMENT

The Great Western Contracting Co., Kansas City, Mo., representatives for the Conveyors Corporation of America, Chicago, have changed the name of their organization to the Rawlings Industrial Equipment Co.

U. S. RECOGNIZE BRITISH EXPERT

Sir Robert Hadfield Brought Out Steel of Great Use During War

Sir Robert Hadfield, inventor of manganese steel and leader of the British steel industry, has been awarded the John Fritz gold medal for notable scientific and industrial achievement, it was announced by the John Fritz Medal Board, of New York, representing five leading United States engineering societies. Manganese steel was first described by Sir Robert in 1893, but it did not become generally known until the war demanded armaments in which toughness was combined with great strength. Manganese steel is non-magnetic, and millions of helmets made of this material were worn during the war by British, United States and Belgian soldiers. In addition to inventing manganese steel, Sir Robert discovered a magnetic steel of high permeability especially suited for use in dynamos and motors.

HAMILTON LODGE C.A.S.E.

The educational committee of the Hamilton Lodge of the Canadian Association of Stationary Engineers have obtained the loan of the new lantern recently purchased by the Grand Lodge of the Order and on February 7 they intend delivering an illustrated lecture on A.C. and D.C. generators and motors. The lodge are actively engaged in a campaign for the acquisition of new members and are making their meetings of such an attractive nature that they feel they will have little difficulty in the matter. At the last meeting a resolution of condolence was passed expressing the sympathy of the lodge with the widow of the late secretary of Toronto Lodge, Mrs. F. C. Harding.

ADVANTAGE OF REDUCED GRATE AREA

Editor, The Power House:

In your December issue of the Power House, page 538, you give some notes from one of my lectures on the establishment of a standard ratio between grate area, gas outlet area from the rear end of the furnace flues and area of chimney. On the second column, third paragraph, you state, "During the last few years many old boilers have been fitted with parallel flues, etc."

The sentence should read as follows:

"During the last few years we have replaced with modern Lancashire boilers many old boilers having parallel flues. Two of such boilers 8 feet diameter are now in our yard, the flues 3 feet in diameter, which is 2 inches less at the front end than in the modern boiler of the same shell diameter, but 4 inches larger in diameter at the back end, but the old type will evaporate 15 per cent. more water per hour than a boiler of modern design and under exactly similar conditions."

W. H. CASMER.

FUELS ON RAILWAYS

Important trials with pulverized coal and "colloidal fuels" have been carried on the Great Central Railway, England. Colloidal fuel is powdered fuel suspended in thick oil, and pulverized coal is dry coal reduced to a fine dust. The trials, which were made in comparison with ordinary coal, showed that the special fuels could easily maintain a full head of steam with a high degree of superheat, even on heavy gradients and sharp curves. Locomotives adapted for burning pulverized coal or colloidal fuel show an economical freedom from ash-pan cleaning, smoke-box cleaning and repairs, fire cleaning, and so on. Further, when the locomotive is delayed in a siding there is much less waste of fuel than in the case of ordinary engines.

DRILLING HOLES IN GLASS

You can drill small holes in glass with a diamond point resembling that used for china riveting, or with a dead hard steel drill, says Practical Engineer. Use a lubricant of turpentine or oil of spike. Large holes can be rapidly made with a piece of copper tube having a serrated edge fitted with crystals of carborundum. It is not the hardness of the glass that causes the trouble, but the heat created by the friction of the drill. It will be found preferable to leave the glass in cold water where the experiment can be carried on, the water preventing undue heating with the consequent fracture of the glass.

C. H. N. Connell, district engineer of the Canadian National Railways, has been promoted to the position of district engineer at Toronto, with jurisdiction over all lines in Ontario. Mr. Connell became associated with the C. N. R. in 1909, when he was appointed engineer of maintenance of way over the Quebec division. In 1914 he was appointed divisional engineer and promoted to district engineer in the early part of 1918.

Walter Lambert, naval architect, 14 Place Royale, Montreal, is now getting prices from Canadian shipbuilders for motor barges for carrying pulpwood and specially designed for shallow draft conditions for mechanical unloading. It is expected, provided prices are acceptable, that contracts for same will be placed immediately, in which case ships will be in service in the St. Lawrence during the coming season, and being of special type will doubtless attract considerable attention. Mr. Lambert hopes at a later date to be in a position to publish plans and specifications of these ships.

ANNOUNCEMENT

The Combustion Engineering Corporation announces the opening of a branch office in Atlanta, Georgia. This office has been placed in charge of Mr. A. A. Hutchinson, who has had an extensive experience in the engineering field and is widely known in the South, having been actively engaged in the field of combustion generally for the past fourteen years and during that period been in charge of important development work.

The Potomac Electric Power Company which operates a number of large power stations in the vicitity of Washington, D.C., employed him as a construction engineer and superintendent of the underground testing department, in which capacity he assumed full charge of several large substations. Mr. Hutchinson later was given charge of the entire testing department. His later experience in the designing, equipping and operating of large power plants has given him an excellent foundation for understanding the requirements of stoker prospects and users with whom he will come in contact in his new capacity.

The Combustion Engineering Corporation believes that Atlanta is a strategic location for handling its southern business and with this office definitely established in the heart of the city at 521 Candler Building, it will be in a position to promptly and efficiently handle any combustion problem in the South.

The Canadian Pacific Railway has announced its intention to offer two free scholarships, covering four years' tuition in architecture, chemistry, civil, mechanical or electrical engineering, at McGill University. The scholarships are open to apprentices and other employees under the age of twenty-one. The necessary requirement will be the passing of the regular entrance matriculation examination provided for in the annual calendar of the University, and the two candidates receiving the highest averages and complying with the requirements for admission will be awarded the scholarships and have the option of taking any of the above courses. Rules governing the continuance of the course provide that the holder shall meet the necessary requirements for the next higher year. Interruption to studies may be granted by giving due notice to the railway company.

Build Coke Plant?—The Semet-Solvay Co., the largest concern of its kind in the world, is considering building a four million dollar by-product coke oven plant at Hamilton, it is announced. It is said this would produce all the artificial gas necessary to meet Hamilton's needs for several years.

Will Develop Plant.—It has been reported that the United States Steel Corp. has voted $291,420 for the extension of the Essex Terminal Railway for running several spurs from the main line of the route into the plant of its subsidiary, the Canadian Steel Corporation.

An Ambitious Proposal

IN this issue of Power House, two schemes which together would be able to utilize the full amount of water available at Niagara and develop between them 4,000,000 horsepower, are described. They are proposed by T. Kennard Thomson, an engineer of wide reputation and achievment.

The two schemes are briefly the cutting of two tunnels through the rock of Goat Island to carry water from the head of the falls to a power house situated at their base, and secondly the erection of a huge dam at Foster's Flats, just below the whirlpool rapids, with a power house below. The combination of these two schemes would give the 4,000,000 horsepower promised. By the canalization of the St. Lawrence a further amount of power could be obtained which would bring the total up to 6,000,000 horsepower and create a great manufacturing centre on each side of the river to the immense benefit of both countries.

The working out of the plans it is suggested should be done by private enterprise, but working under an arrangement by which they could be rewarded according to the cost per horsepower of the power they furnished. That is the cheaper the power supplied to the public the more the power owners would receive. In this way the promoters would have all the incentive to supply power as cheaply as possible and the evils of both government ownership and entirely private ownership without control would be avoided.

The scheme is a big one and requires to be viewed with a total absence of bias. That it is sufficiently practicable to require careful consideration by the governments of both countries seems to us to be obvious. With regard to the existing power houses, it is suggested that they could remain in operation until worn out, but that they would never be replaced, as the entire supply of water could be utilized by the scheme proposed. The money spent on the Chippawa Canal would be lost, but the saving made possible by the generation of enormous amounts of cheap power would more than make up for that.

We wonder what Sir Adam Beck thinks of it and especially the suggestion that the Chippawa Canal should be scrapped at once to save further loss on a scheme soon to be obsolete?

How Could He Do It?

A CORRESPONDENT, after reading an account of a fatal boiler explosion, expresses wonder that a man could be so careless as to light up a furnace without first ascertaining the water level.

This may well seem a strange proceeding, when looked at from the standpoint of the man of average intelligence, but it is just these dangerous lapses from standard, careful practice that account for many of the accidents happening from day to day. It is against carelessness of this kind that the chief engineer of a plant has to guard. He may take every possible precaution, and still be let down by the lack of interest of some one man on his staff, who does not realize his responsibility. Every chief engineer of a plant that employs a night staff has had the experience of being called from his home or from his bed by an S.O.S. from the plant and most of them have found on these occasions that the use of a little common-sense on the part of the night staff might have saved him that trouble. There are, of course, situations that arise that really call for the presence of the chief, but more often than not it is otherwise.

There is again the man who is just foolish, who wanders down into the boiler room and monkeys with things he does not understand. A case of this kind is reported in the Montreal press, where the result was fatal. Some idiot, who should be locked up out of harm's way, went down into the boiler room of a plant and threw a quantity of photographic flashlight powder into the furnace. The explosion that followed caused the death of the fireman and the severe injury of several other persons in the vicinity, among them the thrower of the powder.

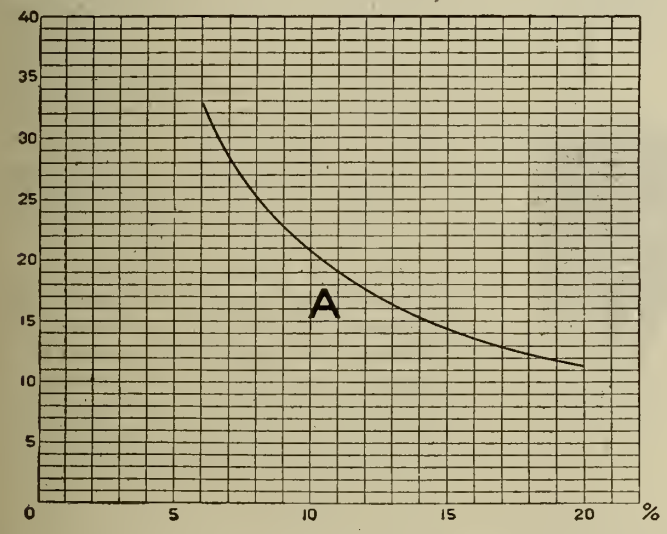
It seems hard to believe that men can be so utterly without sense or thought as to do these things, but we must believe the evidence when we see it. Of all the various mechanisms going to the make up of a power plant, the one unknown quantity still remains. That is the human element. It is an indeterminate quantity and the most reliable of men are sometimes attacked by a species of aberration which leads them to do things they would never do in the ordinary course of events.

In a power plant the secret of successful operation is eternal vigilance, not only on the part of the chief, but of everybody on the job. This "safety first" stuff is not a bad thing to follow out, even if it is sometimes presented in a ludicrous manner.

Progress in New Equipment

A NEW SYSTEM OF GAS ANALYSIS

The Mono Corporation of America has recently placed on the market a new flue gas recorder, which makes a continuous and simultaneous record on one and the same chart of the percentages of CO_2 and of combustible gases (CO, CH_4 and H_2) in the products of combustion. It is becoming more generally recognized that the per cent. of CO_2 alone is not a sufficient guide in avoiding unnecessary combustion losses, and that combustible gases may be lost up the stack with either a high or low percentage of CO_2. Diagram Fig. 1 shows the losses taking place with different amounts of CO_2 and no combustible gases present, while the second diagram, Fig. 2, shows what the losses are before and after a certain critical point C is passed, where the most perfect combustion conditions possible are present. When this point is passed the decreased air supply causes the formation of combustible gases, even while increasing the percentage of CO_2. This point C is constantly varying. The purpose of the duplex mono, as the new instrument is called, is to make a continuous, accurate record of the amount of CO_2 present at all times, and to immediately detect and record combustible gases whenever they appear. It is claimed that the instrument is so sensitive that it will detect and record amounts as small as 1-10 of 1 per cent. of combustible gases in the products of combustion.



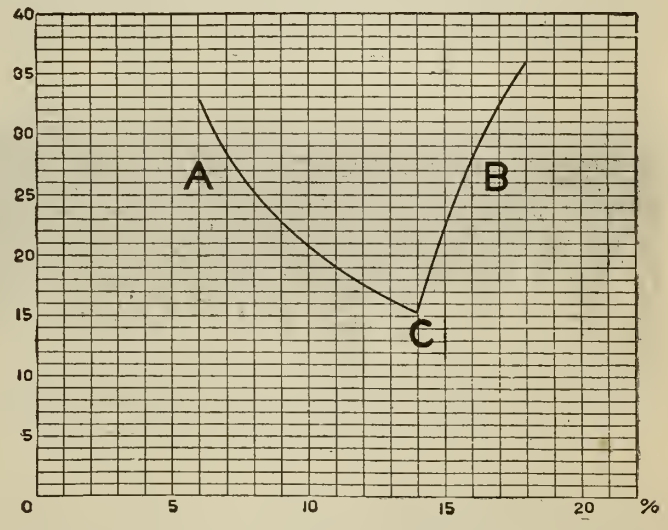


Fig. 3 represents a diagram made by one of these new double-recording instruments. The lower contour of the diagram accurately represents the percentages of CO_2 present at all times. The lighter areas in the diagram indicate the presence of combustible gases (CO, CH_4 and H_2). The proportion of combustible gases present is roughly indicated by the height of the lighter areas at any particular time.

Looking closer at this diagram it will be seen that at the point C, farthest to the left, combustible gases began to form when the per cent. of CO_2 was 10 and the amount of combustible gases formed increased rapidly, as the percentage of CO_2 increased to 11 per cent., only to vanish again when the per cent. of CO_2 was again reduced to 10 per cent. At point C to the right, combustible gases begin to form again, this time, however, when CO_2 is only 8½ per cent. This shows that between 4.30 in the morning and 3 o'clock in the afternoon changes have taken place in the furnace conditions such that while combustible gases began to form when CO_2 was 10 per cent. early in the morning they began to form when CO_2 was only 8½ per cent. in the afternoon. Should the operator keep CO_2 at 10 per cent. all day long, it is evident that serious losses might take place as in this case between 3 and 4 o'clock in the afternoon, as indicated in the right-hand part of the diagram. That is what happens when the maximum allowable CO_2 is determined for an indefinite period by a snap CO test.

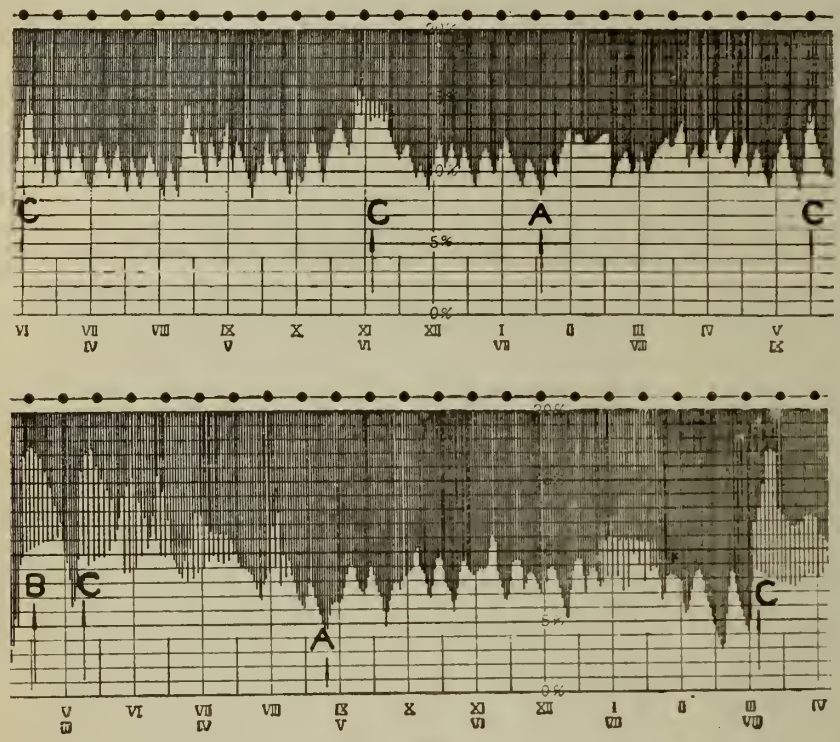
Diagram 3, which we have just discussed, shows the condition found in a boiler plant at the time the instrument was first connected, and the furnace was operated on the old principle. Certain changes were made in the furnace, the nature of the fuel and the method of firing, with the result that conditions as illustrated in diagram 4 were obtained. In this diagram it is seen that CO_2 could be carried to a point as high as 13 per cent. without the formation of CO. In other words, the critical point was raised several points higher on the diagram, the reduction in air supply without formation of combustible gases resulting in a saving of 20 per cent. in fuel. With such a record always before him the operator is always in a position to follow closely any variations in the positions of the critical point and knows immediately when combustible gases begin to escape unburned up the chimney. Where the dark contour goes below the critical point, too much air is supplied, or there is improper distribution of air. Where, on the other hand, the dark contour rises above the critical point, that is, the point where light areas begin to show, the supply of air is insufficient.

General Characteristics of the Instrument

The apparatus (see Fig. 5), is driven by water pressure of about 10 lbs. per square inch. Before entering the instrument, the gas samples from the flue are pulled through a filtering system, which removes all traces of soot and dirt. They are then drawn into and forced through the apparatus by a mercury

piston. There are no mechanical valves, such functions as these ordinarily fulfil being performed by various kinds of mercury seals, traps, etc.

Samples of gas are forced alternately through two routes; one leading directly through a caustic potash tank where CO_2 is absorbed, and the other first through an electrically heated furnace wherein the combustible gases are oxidized to CO_2 and H_2O, and then through the caustic potash tank. Samples that are forced through the caustic potash tank only give the readings for CO_2. Those that are first forced through the electrically heated furnace and then



through the caustic potash tank give readings of CO_2 plus combustible gases. The difference between any two successive readings is proportional to the amount of the combustible gases present at the time the analyses are made.

In the electrically heated furnace, the oxygen necessary to oxidize the combustible gases, CO, CH_4, and H_2 to form CO_2 (which is later absorbed in the caustic potash tank) and water (which is condensed) is usually taken from the air which is almost invariably present in flue gases, even when combustible gases are present. When such free oxygen is not available, oxygen is taken from copper oxide provided in the furnace for that purpose. The copper oxide, however, probably seldom acts as anything but a catalytic agent and need never be renewed.

Should any of the copper oxide be reduced to plain copper to oxidize combustible gases in the process of analysis, it is reoxidized by oxygen present in the flue gas samples passing through the electric furnace later.

To diminish the lag between the time when the gas leaves the flue and the analysis is recorded on the chart, small communicating tubes are used. The lag between the time that the sample is taken from the flue to the time that it is recorded by the instrument is about three minutes where the distance between the instrument and the point where the flue is tapped is about 60 feet and the instrument is making about 40 analyses per hour.

These instruments are made to produce records covering a range of either 20, 25 or 40 per cent., according to the purpose for which they are intended. The 20 per cent. range is the most common. A range shifter can be provided so that the position of the range is adjustable, that is, the 20 per cent. range, for example, can be set between 0 and 20, 5 and 25 per cent., 10 and 30 per cent., or between any other limits at the will of the operator.

The recording pen, when at its highest position, comes into contact with an ink container having a two weeks' supply of ink. The ink in the pen is automatically replenished every time it returns to the high point on the chart.

The apparatus is practically dustproof and requires only a slight amount of attention, which consists in winding the clock once a week, replacing the caustic potash solution two or three times a month, replenishing the ink supply twice a month, and putting in new rolls of paper once every two months.

Accuracy of Records and Their Value

The readings indicating the presence of combustible gases are exaggerated, if anything, by the duplex mono. This is quite an advantage in a danger signal. The losses due to the appearance of combustible gases are much greater than the savings due to an equivalent increase in CO_2 as registered on the chart, and an exaggerated record of their presence on the chart has a favorable effect on the fireman. Since it is aimed never to have combustible gases present at any time anyhow, there would be no object in having exact records of the percentage present where they do appear. An approximate, and preferably an exaggerated, record is all that is necessary, and this is the kind of record made by this instrument.

It is claimed that the CO_2 records of the machine are invariably accurate. This makes possible the accurate determination of the critical point at any time under any conditions. The critical point, C, as mentioned before, is the highest percentage of CO_2 that can be reached in a given furnace without having combustible gases begin to appear. The higher it can be raised, the more economical is the process of combustion. Knowing its maximum from the clear and accurate records of the instrument, the fireman can always tell the degree to which he is approaching ideal conditions. Should combustible gases appear at a point below the critical point, he knows that his dampers, fire doors, or the fire itself needs immediate attention, which experience soon teaches him to give to the best advantage.

The plant executive is given a permanent record which gives him the data necessary to compute the degree of efficiency attained in the firing of the furnaces, and offers him every opportunity to intelligently appreciate the efforts of the firemen. It enables him to give valuable suggestions and advice and to co-operate with the boiler room force most effectively towards promoting fuel economy.

The Meeting of Electric Generator Troubles

Some of the Common Defects of Electrical Generators, Their Cause and Remedy, are Discussed in a Practical Manner in This Article.

By F. A. SWEET

WHEN a generator fails to produce current the cause can usually be traced to the inability of a self-excited unit to build up its field. To start such a unit properly a certain amount of field residual magnetism is required, which must be increased to full strength by the current generated in the machine itself. This trouble is not likely to occur in a separately excited unit, and if it does it is usually due to the failure of the exciter.

The cause of this condition is weak or destroyed residual magnetism, due to vibration or jar, proximity of another current, a strong current through the armature, when there is little or no field current, which tends to neutralize or reverse the field owing to the reverse ampere turns, and accidentally reversed current through shunt or series fields coils which may not be enough to reverse the magnetism completely. Reversal of magnetism will not cause failure to generate. The symptom of this ailment is weak or no attraction when the pole pieces are touched with a piece of iron.

To relieve the condition, send a magnetizing current from another machine through the field coils, then start the generator again. If this fails, change the direction of the exciting current since it may have enough polarity to prevent them building up in the case. Shifting the brushes backward will make the armature magnetism assist that of the field. Change the polarity of the machine so that influence of adjacent machines will have opposite effect.

Another cause to be reckoned with is reversed connections or reversed rotation. An indication of this condition is the fact that while running the pole pieces will not attract a piece of iron. The application of external excitation will not, in this case, make the machine generate because whatever field is built up is destroyed by the armature current.

The remedy is to reverse either the field or armature connections, to move the brushes through 180 deg. for two-pole, 90 deg. for four-pole, 60 deg. for six-pole, etc., or to reverse the direction of rotation. After any of the above alterations the field will have to be excited from an outside source.

Another cause in short-circuiting of either the internal or external circuit which manifests itself in weak magnetism: If the short is in the external circuit it will prevent a shunt dynamo from building its field; but with a series machine the building up of the field will be hastened. If the short is in the machine it will likely prevent the building up of either type. A slight short such as a defective socket or copper dust on the commutator may prevent a shunt machine from building up, as will also an overload.

Field coils opposed to each other are still another cause of failure to generate. The evidence of this condition is the appearance, when tested with a compass, of similar poles adjacent to each other. This state of affairs can be corrected by reversing the connections on the reversed poles.

An open circuit which may be caused by a broken wire or faulty connection in machine, brushes not in contact, safety fuse being blown or circuit breaker being out, or an open switch, will naturally cause failure to generate.

If the trouble is an external open circuit the field of a shunt machine will be fully magnetized and the machine will be working perfectly; but if the trouble is inside the machine, the fields will be weak. A break in the field circuit of a separately excited installation will prevent generation and is indicated by no field in the generator and full exciter field.

A break in a single-phase series-wound armature will result in non-generation, in a two or three-phase "Y" armature will cause it to generate single-phase, while in a delta armature it continues to give three-phase, but at reduced capacity.

To remedy, make a careful inspection for open circuit in both field coils and armature. A break or excessive resistance in the shunt field or field regulator will also make the magnetism weak. This may be detected by cutting out the rheostat for an instant or by connecting the two terminals of the field coils to the brushes in first one and then the other direction.

A high resistance in the circuit of a series-wound machine will prevent building up. Short the machine momentarily to start the field.

Failure to generate may also be caused by the brushes being improperly placed. The tell-tale of this condition is a change in the magnetism and voltage when the brushes are shifted.

It frequently happens that the brushes are not set at the correct point or they may be set at exactly the wrong position, in which case the machine is incapable of delivering any current whatever. This trouble is probably due to the fact that no two machines have the same setting. Drawings should be obtained showing the proper position of the brushes before an attempt is made to set them.

Sparking at the commutator is a common trouble. One cause of this is excessive armature current, due to an overload on the machine, short circuit, ground or excessively high voltage.

To remedy, reduce the load, eliminate the short circuit or ground, or reduce the voltage.

Brushes not set at the neutral point may cause excessive sparking. In this case the sparking will vary when the brushes are shifted. The brushes should be shifted until the trouble disappears. Care should be taken to see that the brushes are exactly opposite.

A commutator rough, eccentric or with high bars will cause sparking, due to imperfect contact of the brushes. A rough commutator should be filed or stoned down, or even taken out and turned if extremely bad. Eccentricity may be in the armature or merely due to a loose bearing. If the former, it should be turned down; if the latter, new bearings should be fitted.

In order that the commutator should wear smooth the shaft should be allowed end play of about ⅛ inch.

Other causes of poor conductivity at the brushes are dirty or oily brushes, a glass hard brush which is incapable of wearing to a good seat, or a brush that has a high specific resistance.

The remedy is to clear the fouled parts and replace poor brushes.

A short-circuited or reversed coil in the armature will cause sparking, which condition can be noticed by the excessive power required to run the generator without load. The short-circuited coil heats faster than the others and is likely to burn out unless promptly attended to. A piece of steel held between the pole pieces near the armature will vibrate as the defective coil passes.

Such a short is often caused by a piece of solder or other metal getting in between the commutator bars or their connections. The trouble is easily found and remedied. If, however, the short is in the coil itself the only reliable repair is to rewind the coil.

A broken armature circuit will cause violent flashing and the bar nearest the break will be badly burned. A poor contact somewhere in the circuit will have this same effect to a lesser degree.

Such a break or poor contact may be located by the drop of potential or continuity test. The break is usually in the connections between the coil and bar, where it can be readily repaired. If it

is in the coil the only remedy is to rewind the troublesome part.

A ground in the armature will often cause sparking. When two or more grounds occur in the armature the result is a short circuit and the case should be so treated. A single ground on electric railway line or a three-wire system with the neutral wire grounded will have the same effect.

To find the ground wrap a flexible conductor around the commutator. Apply a current through this connection and the shaft. If a ground is present a current will flow and the defective coil will be energized. It can then be located with a compass.

A weak magnetic field causes sparking. The tell-tale of this condition is weak pole pieces and the point of least sparking is shifted considerably from the normal position. Full voltage or current is not forthcoming.

The causes of this condition are (1) a broken circuit, which may be found by opening the field circuit after having insulated the field; if no spark occurs there is a break some place in the circuit; (2) short-circuit; (3) grounding, which may be found by drop-in-potential method.

A broken circuit is easily repaired if accessible; if it is in the coil the coil will have to be rewound. If the circuit voltage is low, sparking will result. If it cannot be raised the field resistance should be reduced by unwinding a few layers of wire.

Flashing over is a spark jumping from one set of brush holders to another or to the frame. This is caused by poor or insufficient insulation between the points mentioned or by deposits of copper or carbon dust on the surface of the insulation. This latter is the usual cause and the trouble can be eliminated by simply cleaning the parts with an oily cloth.

Ring fire is an exaggerated case of commutator sparking and may cause flashing from one set of brushes to the next. The remedies for commutator sparking will obviously do away with this trouble.

Any of the causes of sparking will cause heating of the commutator. In fact, heating frequently occurs from these causes before sparking is noticeable.

The next in importance is heat spreading from other parts of the machine. The machine should be started when cool and run for a few minutes, then a search made for warm parts before the heat has a chance to radiate to the rest of the machine.

These parts should be attended to as directed under their respective headings.

An overheated commutator will cause deterioration of the brushes and cover it with a black film, which offers more resistance and aggravates the trouble. The commutator should be cleaned and the different brushes fitted if necessary.

Brush connections may offer abnormally high resistance, which may be tested by the drop of potential method and improved.

Heating will occur when there is an arc or short circuit between bars or between bars and end ring. The arc will be noticeable when the machine is runing. Burnt or otherwise defective insulation should be taken out and replaced.

Brushes of high specific resistance will produce heat. Better carbons or greater conductivity should be installed.

The friction of the brushes will also produce heat. This case can be differentiated from the preceding one by noting whether or not the temperature is excessive when the current is light. This may be due to heavy pressure or high speed. Reduce the spring tension. Decrease speed, but keep up the voltage by increasing the field. Lubricate slightly with oil or vaseline.

Excessive current will cause heating of the armature as will also moisture in the coils. Moisture can be detected by steaming when hot. The armature should be taken out and baked for several hours at a temperature sufficiently high to drive out the moisture, but not hot enough to injure the insulation.

When the iron of the armature core is found to be warmer than the coils after a short run and when considerable power is required to turn the armature when there is no current through it and when the field is connected, indications are that there are eddy currents in the core. There is a question of poor lamination and a matter of primary construction.

Reversed coils in one part of an armature will cause local currents to circulate around a direct-current armature, causing a rise in temperature. This will mean excessive power to drive a generator without load. A compass will indicate the reversed coil when a current is sent through each coil separately. The remedy lies in simply reconnecting the terminals to agree with the rest.

Excessive current in the field circuit will bring about heating of the field magnets. A temperature of 122 deg. F. above room, as determined by a resistance test, is considered high.

In the case of a shunt wound or separately excited machine, decrease the field voltage or increase the resistance. In the case of series winding, shunt a portion of the current. This condition might be cause by a short circuit, in which case the defective coil will be cooler than the others. As a check measure the resistance of each coil; if there is any considerable variation the low resistance coil is sure to be grounded or short-circuited.

In alternating or pulsating current work the field pieces will become heated, due to eddy currents unless they are carefully laminated.

Moisture in these coils will cause short-circuiting and heating, as in the armature.

Heating of bearings is a condition to which any machine not properly constructed or attended to is subject. In cases where a stop for repairs would be fatal, temporary relief may be had by pouring cold water on the bearing or packing it in ice.

This state of affairs is usually due to lack of oil. The oil passages may be clogged, the reservoir dry, the oiling devices out of order. These defects should, of course, be remedied. Use good oil. It will be money well invested.

Grit in the bearings will cause heating. Remove the bearing and investigate for foreign particles. Scratches will be noticed. Remove the dirt, clean the bearing, use clean oil and provide a dirt-proof casing if necessary.

A shaft that is rough, scored, or too large will also cause heating. It should be turned down in a lathe and refitted.

A sprung shaft presents difficulties in truing and a new one is usually necessary.

A shaft turns hard and heats when the bearings are out of line. Conditions are relieved by loosening the holding bolts. Bolt the bearings in a position where the shaft turns freely, being sure that the armature is in the center of the field.

Thrust of a shoulder or the shaft against the bearings will generate heat and is caused by the belt drive being out of line or by the armature not being centered axially with the field coils. The remedy will be found in lining up the belt or moving the collar to allow the shaft to center itself.

Too heavy tension on the belt or eccentricity of the armature will cause an extra load on one side of the bearing and heating of the bearing which will wear elliptical in time and aggravate the trouble due to an eccentric armature. The belt tension should be decreased, using a larger pulley if necessary, and the armature should be centered. If the bearings have worn elliptical, new ones should be fitted.

The most frequent source of noise is the humming, squeaking or hissing of the brushes on the commutator. This trouble can readily be located by the ear. File or dress the brushes down with sandpaper and apply a little oil or vaseline. Changing the length of the brushes and the pressure often helps.

Vibration due to the revolving armature, field, pulley or commutator being out of balance is, of course, objectionable. The parts should be taken out and balanced, separately, because a static balance of the whole combination is not likely to prove to be a dynamic one. A dynamic balance takes place only when equal moments are directly opposed to each other.

When the armature rubs against the pole pieces, noise results. Bind down any abnormal projection on the armature; center the armature; chip off high spots on the field pieces.

Noise caused by the collar or pulley rubbing on the bearing is due to the

FAIRBANKS-MORSE

The 100% Quality Mark is Your Protection

FROM the Atlantic to the Pacific and into the frozen North, you will find abundant evidence of the confidence in which The Canadian Fairbanks-Morse Co., Limited, and its products are held,

The fisherman with his little boat, equipped with a Type "M" Engine, the coastwise boat with its "C-O" power, the farmer who has solved his labor problem with Fairbanks-Morse power farm equipment, in every great industry—mines, mills, factories and railways, Fairbanks-Morse products are used.

The presence of Fairbanks-Morse mechanical equipment everywhere is the real tangible evidence of confidence that is placed where quality counts and in service that brings seller and buyer together in a closer relationship which builds for the benefit of all.

This is the reason that The Canadian Fairbanks-Morse Co., Limited, has adopted the 100% quality seal as its standard.

When you place an order with any salesman you are buying both service of product, and service of organization.

Our experts are always ready to help work out your problems and are always as close to you as our nearest branch house.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

CLEANING A BOILER

Question.—Would you recommend the use of sal soda to remove soft scale from a boiler. Should it be fed through feed water and if so how much?

Answer.—Sal soda is generally a very safe and economical material to use for the purpose of softening scale and keeping boiler clean. The quantity that should be used will depend entirely on the amount of water that is being evaporated daily, as on this depends the amount of solid matter that will be deposited in the boiler. If your boiler is 60 H.P. and you are running ten hours a day, about one pound of sal soda per day should be ample. However, you would have to determine the necessary quantity by experiment unless you know the exact analysis of the water. With soft scale such as you mention, it is well to be careful about using too much soda, as when your boiler is banked at night and circulation is practically stopped, the sediment is very liable to deposit in one spot, causing a burnt plate. In operating a locomotive boiler such as you mention it is well at first to open it up frequently and determine the condition, from which you can judge as to whether you are using enough soda or otherwise.

To remove the scale before starting up, fill the boiler with clean water and add about ten pounds of sal soda. Leave the manhole door off and heat boiler up gently till water boils. Keep a very light fire, just enough to keep the water simmering for two or three hours. Then let the fire die down and let the boiler stand for a couple of hours more. Then open the blow down cock and let the water drain out, and if possible have a hose and follow the water down with the hose. That is, as the plates, etc., become bare, wash them off with the fresh water from the hose. This prevents any sediment sticking to the warm plates as the water subsides. In this manner you can get even a very dirty boiler clean, and should have no trouble with a boiler such as you mention.

When running and using the soda daily, do not use the blow down cock too much. It is well to blow a little water out to keep the blow off outlet clear, and to remove any sediment that may accumulate in the bottom of the boiler. However, dont forget that all the water you blow out has to be replaced with water that also contains sediment, so that you may easily be adding more sediment than you blow out.

A SHIFTED ECCENTRIC

Question.—In a marine engine, if your go-ahead eccentric sheave slipped on the shaft when under way, what would be the quickest way to adjust it? What would cause a clattering noise in the cylinder of a vertical ammonia compressor?

Answer.—A simple way of adjusting the strap would be to place crank on top or bottom center and open drain cock on cylinder either at top or bottom, whichever end crank is at. Turn eccentric sheave around with link in ahead position, until the spindle has travelled to the end of its stroke and starts coming down again. Crack main stop valve so that a wisp of steam can leak through and turn eccentric round till steam shows through the drain cock. The valve is then open to steam and eccentric is in nearly the correct position. Another way is simply to turn sheave around until it is as nearly as you can judge at 120 degrees ahead of the crank, and try your engine at that. The first method is in the long run the quickest. If you have a turning gear fitted ship it before starting to set your sheave. If there is no turning gear block the crank so that it can't turn.

* * *

PUMP NAME PLATES

Question.—On all pumps air compressors, etc., the maker puts a plate with the dimensions, length of stroke, etc. Is there any hard and fast rule for reading these. If so in what order?

Answer.—It is usual to put first the size of steam cylinder, then the size of water cylinder, and lastly the stroke. For instance, on a boiler feed pump the plate might read 2x1½x2¾ in., which would mean a steam cylinder of 2 in., a water cylinder of 1½ in. and a stroke of 2¾ in. If the steam part of the pump is a compound arrangement, the cylinder sizes will be given with the high pressure first, then the low, followed by the water end cylinder sizes, and lastly the stroke. The same rule applies to air compressors, the first sizes given being the steam end, then the air end, and lastly the stroke.

* * *

BOILER HORSE POWER

Question.—A plant having four water tube boilers said to be 360 B.H.P. each, two of them only are working at one time and two are dead, for repairs, cleaning, etc., never any more than two in operation. What is the B.H.P. capacity of plant? I have been told that it is 1,440 B.H.P. Is that right?

Answer.—The B.H.P. capacity of the plant is the total rated capacity of all the boilers in the plant. You have four boilers of 360 H.P. each; then the plant is 1,440 H. P. The fact that you do not avail yourself of the total capacity does not decrease that capacity.

GENERATOR TROUBLES

Continued from page 34

same condition that causes bearings to heat, and should be so treated.

Rattling due to the looseness of parts can be eliminated by careful inspection of the machine before or after each run. Tighten up the loose parts. Replace a poorly fitting bearing.

The flapping of a belt joint on the pulley produces a disagreeable sound which should be stopped by making a better joint.

An intermittent squeaking sound which indicates a slipping belt may be overcome by increasing the tension of the belt or by applying a belt dressing.

The humming of the armature core teeth as they pass the pole pieces ought not to occur if the machine is properly constructed. It can be relieved by sloping the edges of the pole pieces.

Humming due to alternating current is inherent to a large extent in alternators, but can be deadened by mounting the machines on felt or some such material.

Improper voltage is a common difficulty which may arise in any machine, and is due to the following causes: Field magnetism too strong or too weak; brushes not in proper position; generator overloaded; short-circuited or reversed armature coils.

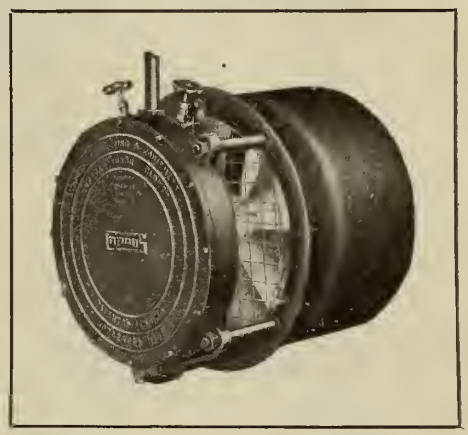
All of these produce sparking and are dealt with under that head.

Speed too high or too low, or open, short-circuited or reversed field coils may prevent a dynamo from generating current.

A direct or alternating-current generator, unless it is compound or composite would tend to fall in voltage with increased load. This is usually overcome by raising the field current or by cutting out field resistance.

COPPUS TURBO BLOWERS

In Use in Large Canadian Steam Plants



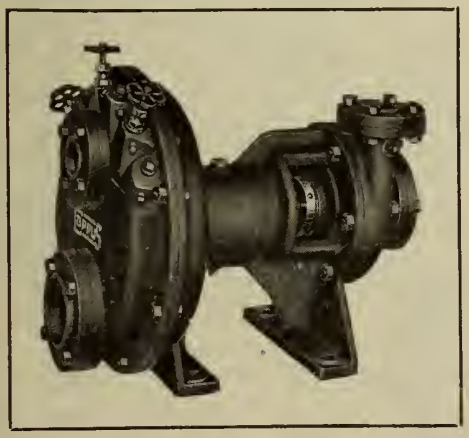
MORE and more records made by *Coppus Turbo Blowers* in the steam plants of well-known Canadian industrial and public buildings prove their *efficiency* and *economy*.

SOME PROMINENT USERS

The T. Eaton Company, Ltd., Hamilton.
Canadian National Railways, Leaside, Winnipeg.
Farmers' Dairy Co., Toronto, Indian River.
Lever Bros., Toronto.
Simpson Knitting Co., Toronto.
St. Michael's Hospital, Toronto.
Davis Leather Co., Newmarket.
Municipal Abattoir, Toronto.
Davisville Hospital, Davisville.
Orthopaedic Hospital, Christie St., Toronto.

Boilers are consistently operated at high over-rating where Coppus Turbo Blowers are installed. More steam is produced, greater efficiency, greater returns from capital invested in boiler room equipment. Fuel troubles never bother where Coppus Turbo Blowers are at work. The worst coal is burned under boilers with almost perfect combustion and thorough efficiency.

Interchangeable parts, standardized; the perfected oiling system; the expanded fan casing, and the protection of bearings and oil system against dirt and grit helped in making Coppus Turbo Blowers miracles of steam economy.



Coppus Turbo Boiler Feed Pumps

Coppus Turbo Boiler Feed Pumps supply water to the boilers at a similar low steam consumption, in proportion to the heavy duty which they are called upon to give, to that which characterizes Coppus Turbo Blowers.

Coppus Turbo Boiler Feed Pumps are particularly effective in lengthening the life of piping, valves and boilers by furnishing an even, steady pressure entirely without the deteriorating effects of water hammer.

We are prepared to solve your combustion problems and explain fully the benefits of COPPUS TURBO BLOWERS and COPPUS TURBO BOILER FEED PUMPS. Did you get your copy of the new Coppus Catalogue?

Are You Troubled With Production Losses Due to Faulty Valves?

Mason Regulating Appliances

Will Stop All Leaks

THERE is no reason to go on wasting steam and money by using inefficient valves. Get in touch with a Mason engineer. He will show you the economical way of installing Mason positive acting appliances. He will explain the substantial saving this will net you.

Mason appliances are to-day the choice of thousands of Power Users. In the most critical positions—where absolutely even pressure is demanded—Valves and Regulators of Mason design are fulfilling their purpose with steadfast reliability and a minimum of attention.

Mason Standard Reducing Valve Iron Body

Mason Standard Bronze Reducing Valve

If you are concerned with results we heartily welcome your enquiries. We handle Valves and Regulators for every purpose, and our Engineers are always ready to offer assistance.

CHANGE OF ADDRESS

A REQUEST FOR CHANGE OF ADDRESS must reach us at least thirty days before the date of the issue with which it is to take effect. Duplicate copies cannot be sent to replace those undelivered through failure to send this advance notice. Be sure to give your old address as well as the new one.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS VACANT

ENGINEER QUALIFIED TO TAKE CHARGE of Saw Mill Power Plant; only competent man need apply; duties to commence immediately. Apply Box 24121, "Power House." P.F.H.

WANTED—A1 GENERAL BLACKSMITH FAMiliar with mine and mill work; permanent position. Apply, mentioning "Power House," stating experience and wages wanted, to Moose Mountain, Ltd., Sellwood, Ont. (pfh)

EQUIPMENT

THE JOHN INGLIS CO., LTD., ENGINEERS and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention "Power House."

WE BUY IDLE EQUIPMENT OR MACHINery; call or write. Apply, mentioning "Power House," to H. W. Petrie, Ltd., Toronto.

OIL ENGINE — BLACKSTONE. 8½ IN. diameter, 16 in. stroke, 16½ brake horsepower; fly wheels, 5¾ in. face x 4 ft. 10 in. diameter; in complete operating condition. Apply, mentioning "Power House," to Henry Engineering Co., 71 Bay St., Adelaide 3466. P.F.H.

WANTED — MOTORS AND ELECTRICAL equipment. Apply, mentioning "Power House," to Industrial Engineering Co., 28 Wellington West, Toronto. Phone Adelaide 5817.

PORTABLE BOILERS—LOCOMOTIVE TYPE on wheels; each 15 horse-power with engines mounted on boilers; can get Government certificates for 90 and 100 pounds working pressure; cheap; also 40 horse-power high speed Leonard automatic engines. Apply, mentioning "Power House," to Henry Engineering Co., 71 Bay St., Toronto. Adelaide 3466.

BELTING

4½—4-PLY NEW CANVAS STITCHED BELTing at 30 cents per foot. We carry a complete stock of belting, pulleys and mill supplies. Apply, mentioning "Power House," to N. Smith, 138 York St., Toronto.

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto.

WE HAVE A QUANTITY OF NEW RUBBER belting to sell at less than half price; will ship C.O.D., subject to inspection; new circular saws, good second-hand leather and rubber belting, wire cable, vises, chain blocks, garden hose, steam hose, rubber packing; send us your requirements; our quotations will surprise. Apply, mentioning "Power House," to The York Belting Co., 115 York St., Toronto, Ont.

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House."

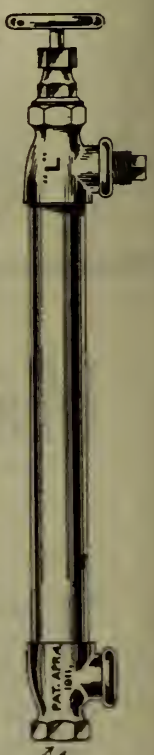
If wrong, tear it off and return to us with correct address plainly written.

Requires Very Little Attention

Do you want efficient and reliable steam trap service without having to give the trap constant attention? Then adopt

The Long Patent Steam Trap



Has important features which CLAIM your attention. Absolutely guaranteed. The Long Trap is automatic and requires no valves except those which control the admission of steam to the apparatus to which the trap is attached.

The trap is regulated to work against any pressure between 1 and 200 pounds. Being open at starting, it cannot become air bound, this doing away with air cocks or vents — Does Not Freeze.

It is capable of draining from 900 to 1,500 feet of one inch pipe.

The Long Trap may be applied to drain steam mains, jacket kettles and separators, and can also be used in drying room systems.

NON-CORROSIVE CYLINDER OIL

MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 24 & 224 SOUTH ST. NEW YORK, U.S.A.

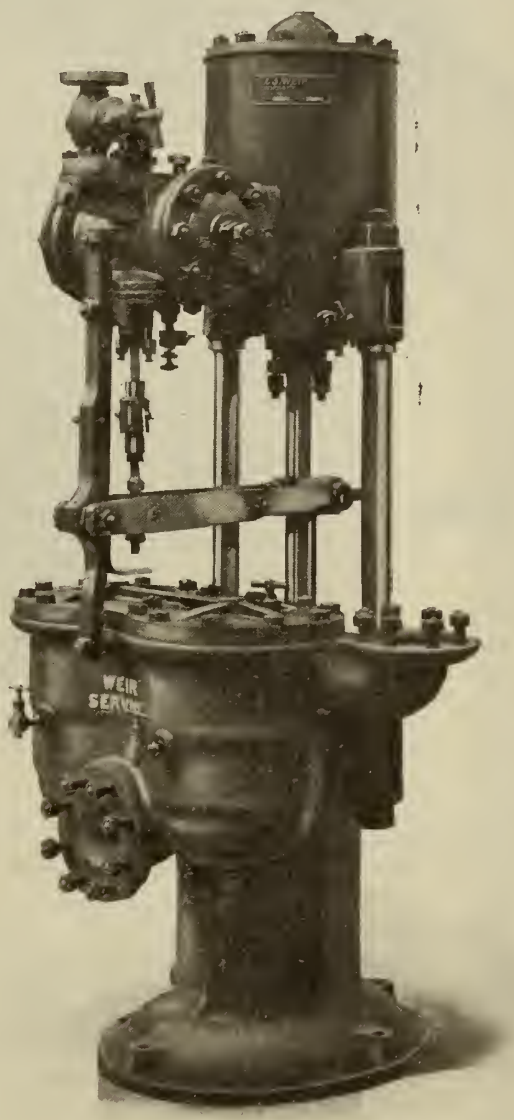
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

Weir Products

Single Acting Simplex Feed Pumps
Turbine Rotary Feed Pumps
Compound Feed Pumps
General Service Pumps
Direct Contact Heaters
Multiflow Heaters.
Evaporators and Distillers.



Built to Absolute Standards

EACH part of every Weir power plant auxiliary is built to an absolute standard. This guarantees uniform results from all products and also enables repairs to be made with as little delay as possible.

The value of facilities for making quick repairs can hardly be over-emphasized. Consider these features of Weir Products when purchasing power plant auxiliaries.

Special attention is paid to the prompt dispatch of goods and the routing and shipment of all consignments. Special instructions in this regard always receive our most careful attention.

Prompt and careful shipment is but a single phase of Weir Service. To serve our customers in every way to the best of our ability is our aim.

DEVIL'S PUTTY

The Way to Greater Coal Economy

Recent discoveries have led to the production of a jointless fire brick which can be molded into the furnace and then baked into a solid lining. The advantages are obvious. No heat can escape—no joints to start disintegration—no cracks to hold clinkers.

PLIBRICO
JOINTLESS

FURNACE LINING

forms one massive heat-resisting setting which expands uniformly, preventing cracks and breaks. It remains heat-tight under modern high temperatures up to 3100 degrees F.

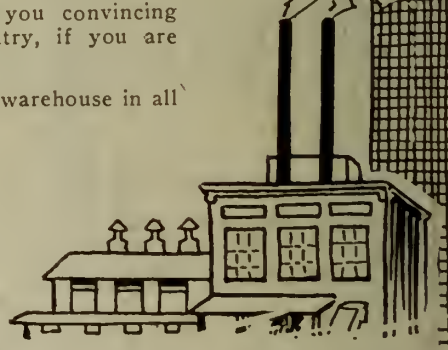
Plibrico has been thoroughly tried out. We can send you convincing endorsements from some of the largest firms in the country, if you are interested.

Shipped promptly in large steel containers from our nearest warehouse in all principal cities.

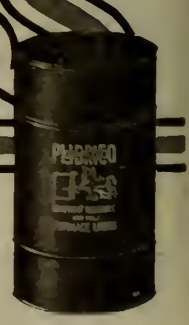
Plibrico is used in every case where laid up fire brick is used and with better results. Try it on a front door arch or wall and the saving effected will demonstrate the greater value of a complete Plibrico setting.

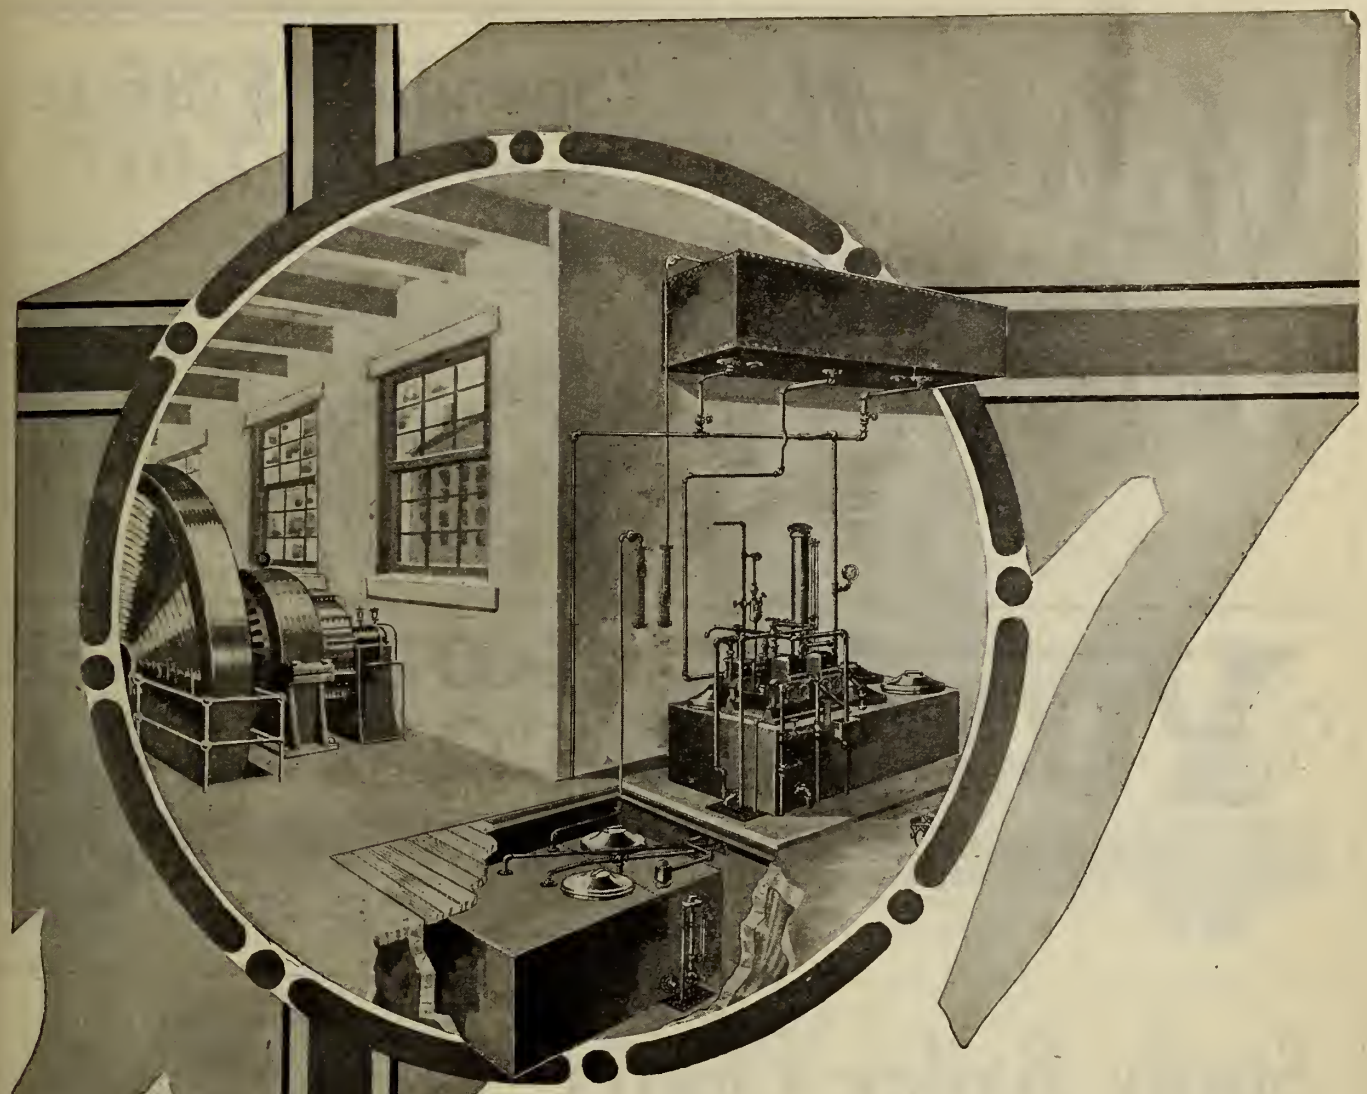
Send for our booklet on furnace building.

(2)



JOINTLESS
FIRE BRICK CO.
1130-1150 CLAY ST. CHICAGO.





Save Fuel by Reducing Friction

Much of the friction on engines is due to irregular hand feed lubrication or using oil which is dirty and contains impurities. This increased friction necessitates the consumption of more coal to produce the required power.

Reduce this friction by installing a Bowser Stream Feed Circulating and Filtering System.

A close study of operating costs in power plants has proved conclusively that there is a reduction in friction and a saving of approximately 5 per cent. in the fuel costs where stream feed lubrication is in practice as compared with hand lubrication methods.

In a plant of only ordinary size, a year's saving in the reduced friction will pay for the installation of a Bowser Stream Feed Lubricating and Filtering System.

Write for our illustrative booklet showing our various filtration systems.

Vulcan Performances

"Spending $796 to earn $1017.40!"

ALMOST any business manager will agree to an expenditure of $796 provided he can be shown some assurance that it will return $1017.40 per year.

Improbable as such a return may sound on its face, it is nevertheless a fact that can be demonstrated, that Vulcan Soot Cleaners will pay more than 100 percent on their investment, depending upon boiler size, cost of fuel, conditions of operating service, and that intangible thing—human nature.

"SPENDING $796 TO EARN $1017.40!" is the title of a folder just issued, explaining mathematically how Vulcan Soot Cleaners pay their way—and a profit, besides.

Send for your copy.

Vulcan Soot Cleaners are built for every type of water tube and fire tube boiler, superheaters and economizers. For estimate of cost for installation in your boilers, state name of boiler, number of tubes high and wide, boiler pressure available, if equipped with superheater, and alley space at sides. Special Bulletins describing Vulcans for various types of boilers will be sent gladly upon request.

Study Bailey Charts
They Will Save You Money

Bailey Fluid Meters are a true necessity to determine the steam consumed by the main power generating units, the auxiliaries, the heating or drying system, special process work, by the various factory departments and outside purchasers of steam.

They accurately indicate, record and integrate steam flow on all pressures and temperatures without constant recalibration or repairs.

Study Bailey Charts. The elimination of even slightly abnormal operating conditions may mean the saving of many dollars in coal and labor.

Write for bulletins.

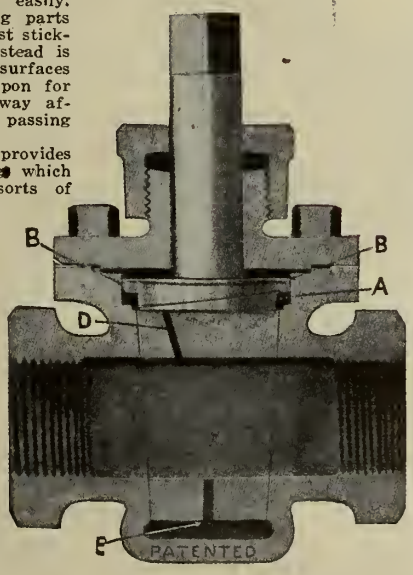
"Homestead" Quarter Turn Valves

Embody Every Detail of Efficiency and Economy

They open and close easily. The patented balancing parts insure this valve against sticking. When the Homestead is fully opened the two surfaces which are depended upon for tightness are in no way affected by the material passing through.

The "Homestead" provides a straight-way opening which is desirable in all sorts of work, but is particularly important in high-pressure service. It is very useful when thick, heavy liquids are handled.



Catalog upon request.

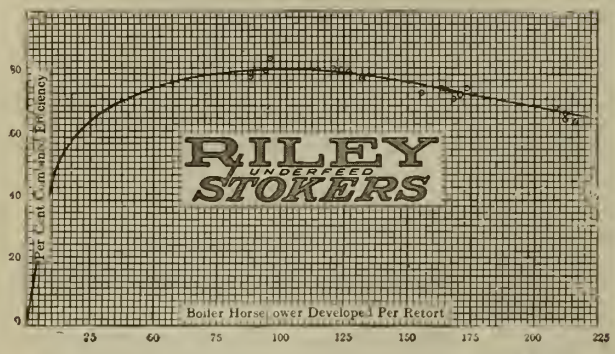
ARE YOU WASTING COAL?



If your boilers are operating at 65% efficiency, whereas you ought to be getting 75% or 80%, then you should investigate to-day the possibilities of RILEY UNDERFEED STOKERS.

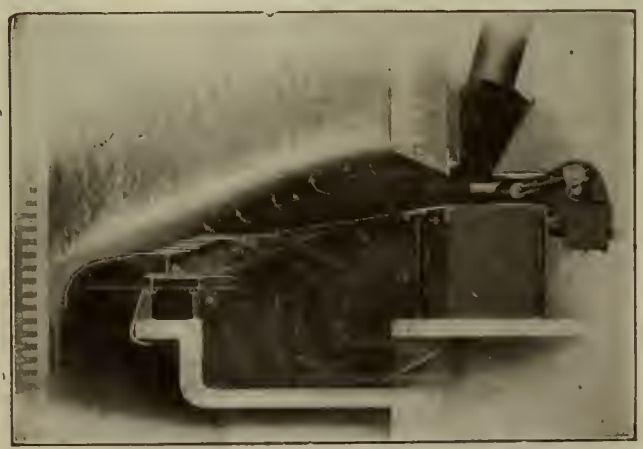
The first year after installing Riley Stokers' the Haverhill Boxboard Company saved ten tons of coal a day, and reduced their operating force by thirty-six men—a total saving of $52,000.00.

Our catalog shows a cut of an evaporation curve. From it you can figure just what you can actually save in dollars and cents by increasing your efficiency.

Catalog HR-2 sent on request.

For information on Murphy Automatic Furnaces for small boilers, see Sept. 20 advertisement, or send for Murphy Furnace Catalog HM-2.

Sanford Riley Stoker Co.
Worcester, Mass.



YARWAY PRODUCTS

are being used in thousands of plants. They are sold under a money-back guarantee.

The Scranton Coal Co. has installed twelve YARWAY BOILER SKIMMERS, four of which are shown on the right. Their Dickson City (Pa.) colliery appears above.

Speaking of RESULTS

The Scranton Coal Co., in a letter from its division superintendent, says: "Since the installation of the YARWAY SKIMMERS a little over a year ago, we have had no further trouble with scale formation, either on shells or tubes. No trouble to wash out boilers now as we find them clean, with no trace of scale. Requires only about one-third of the time and labor compared with our trouble when using compounds. Cannot speak too highly of the results we are getting from the Skimmers."

YARWAY

BOILER SKIMMER

(A continuous, circulating surface-blow)

Removes scale-forming impurities and foreign matter from boiler feed-water before they can settle on shell and tubes, except in unusual cases where certain mineral salts are carried in solution. If you will advise us of your water conditions and the type of your boiler, we will tell you frankly whether or not you can use a YARWAY BOILER SKIMMER to advantage.

Before Spring Comes

THE time to put Nonpareil Cork Covering on brine and ammonia lines is right now when they are dry and free from frost. The job will cost you less and will be much more satisfactory than if you wait until summer.

Nonpareil Cork Covering is easy to apply because it is made in accurately molded sections for all sizes of pipe and fittings. Except for a few simple tools everything needed is supplied with the covering. Any reasonably careful workman can apply it properly, quickly and inexpensively.

Nonpareil Cork Covering in the plant of the Sinclair Refining Company, East Chicago, Ill.

Send in your name to-day for "Nonpareil Cork Covering," a 64-page book on pipe line losses and insulation. It is filled with data—tables and information not available elsewhere—valuable wherever refrigeration is used. Without charge or the slightest obligation, his book will be mailed promptly on receipt of your request.

Nonpareil Cork Covering will prevent approximately 80 per cent. of pipe line losses and save enough refrigeration to pay for itself in a year or less. It will eliminate drip from the lines. It will not absorb moisture or deteriorate in any way. Properly applied and reasonably cared for, Nonpareil Cork Covering will "last longer than the pipe."

ARMSTRONG CORK & INSULATION COMPANY 902 McGILL BLDG., MONTREAL, QUE., CAN. 11 CHURCH STREET, TORONTO, ONT., CAN.

Also manufacturers of Nonpareil Corkboard Insulation for cold storage and ice storage rooms; Nonpareil High Pressure Covering for steam lines, feed water heaters, boilers, etc.; Nonpareil Insulating Brick for boiler settings, furnaces, ovens, etc.; Nonpareil Cork Machinery Isolation for noisy machines; and Linotile and Armstrong's Cork Tile for floors in offices, residences, etc.

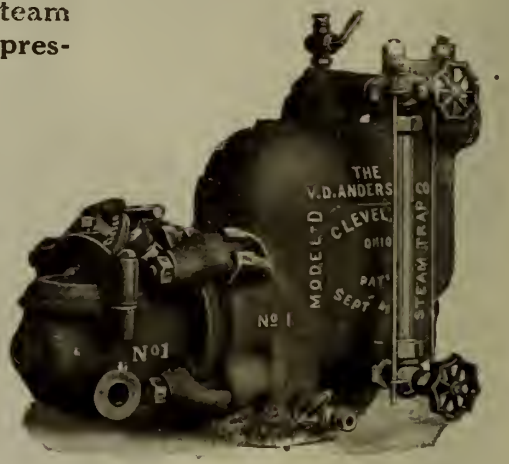
The Anderson Model "D" Steam Trap

Disposes of condensation as fast as it accumulates in steam coils, jackets, radiators, etc., without reducing the pressure or permitting live steam to escape.

All parts are machined to solid gauges, thus ensuring absolute accuracy.

The trap is so constructed that you can change the valve and seat from high to low pressure or vice versa in five minutes without disturbing or unscrewing a single steam joint or pipe connection.

A removable strainer is part of the equipment. It prevents pieces of scale, packing, etc., from entering the trap.



We have a catalog to send you, containing a full description of the Anderson Steam Specialties. Write to-day.

The V. D. Anderson Company

1935 West 96th St., Cleveland, Ohio

Get the Maximum Power from the Fuel You Use

THE fundamental purpose of the boiler setting and the refractory lining is to keep the furnace heat in and the cold air out. Cold air inleakage checks the fire, cools the gases before combustion is complete and sends a large percentage of the heat units of your coal up the chimney.

Separate fire bricks are little more than in place with fire clay when the heat begins to move them.

BETSON'S

REG. U.S. TRADE MARK PAT. OFF. PLASTIC FIRE BRICK

should be used to form in place a one-piece, jointless, monolithic furnace lining, including front arch and walls, side walls, bridge walls, combustion chamber and back arch, if any. Also, gas tight baffles should be formed of these same materials. Then you will not only be getting the most out of your fuel, but you will cut your repair bills to the minimum and will avoid the delays and shutdowns too often necessary with other types of boiler furnace linings and baffles.

We have an interesting and instructive pamphlet dealing with the uses for Betson's Plastic Fire Brick. Write for it.

The Question of ECONOMY

OF A ROD PACKING LIES IN THE LENGTH OF SERVICE, AND NOT ITS FIRST COST

"PALMETTO"

gives longer service than other packings because it is made of a grade of asbestos usually considered too good for packing, but which needs no additional vegetable substance to give it the necessary strength at the expense of its heat-resisting quality.

TWIST
for valves.

"PALMETTO"

does not become hard like other packings, because each single strand has lubricant forced into it before braiding, which lubricant not only keeps it soft but so lubricates the rod as to prevent friction and wear of both rod and packing.

BRAIDED
for rods.

Let us send you sample of both braided and twist to test—no charge.

Boiler Repairs Reduced by Superheating—

Overworked boilers are an expense.

Repair bills and delays are constant sources of worry when insufficient boiler capacity prevents shutting down once in a while to relieve a boiler of its load and to clean it properly.

Such conditions can result only in a forced shutdown, with its attendant expense for repairs and costly delays in production.

By applying Elesco Superheaters you obtain sufficient additional boiler capacity to enable you to draw a fire and rest a boiler. Your maintenance and repair bills are reduced.

Boilers equipped with Elesco Superheaters cost less to maintain.

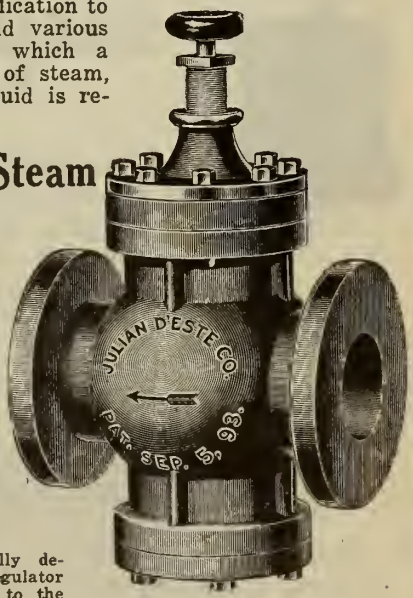
CURTIS Engineering Specialties

Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the



Improved Steam Pressure Regulator

has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip for leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian funds are accepted at par at Montreal.

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

CYCLONE GRATES

No Clinkers—No Waste

You can burn screenings and low-grade soft coal satisfactorily if you are a user of Cyclone Grates. Their scientific design ensures perfect combustion even when low-grade fuels are used. Their 60% air space and 90% under-draught means no clinkers—no waste! Their jarring, shaking movement sifts all the ashes through—the good fuel remains. Write for particulars of our 30 days' free trial offer.

Note:—Have you details of our new pin-hole grate bars for burning hard coal screenings?

The Chart that Protects the Plant from Waste

Just as the chart protects the ocean liner from running onto rocks, the boiler-room is protected from the rocks of waste by the chart of the Hays Recorder.

In many plants, changing from night load to day load is attended by a period of low efficiency and much waste of fuel. Not so in the Hays equipped plants. Hays Charts keep firemen so well informed about conditions of their fires, draft, etc., that they are able to steer away from wasteful practices.

The above chart shows intelligent firing. At 8.15 a.m. the draft was doubled to carry the day load and the CO_2 started to drop—but the fireman saw what was happening—and increased the thickness of the fire, thereby bringing the CO_2 back to 15%. The Hays Chart supplies accurate and timely information, essentials to intelligent firing.

Let us give you a few facts on the importance of combustion efficiency in your boiler-room.

Awarded Certificate of Merit by Franklin Institute.

LINCOLN ARC WELDING

In Your Shop or Factory have you considered

the value of a Lincoln Electric Welder?

In the Steel Mill, Foundry, Machine Shop, the Railroad Shop, or the Shipyard, the Lincoln Welder has saved money, time and needless worry.

The Lincoln, as of course you know, is an electric welder of high merit. It is "backed up" by all who use it and those who have seen it at work.

Have a Lincoln engineer come to your establishment and give you a demonstration of its capabilities. Let him make experimental welds, which we know will give you a new idea of the Lincoln Arc Welder.

We know what it can do, and will be glad of an opportunity to prove it to you.

Belliss & Morcom Motor-Driven Air Compressor

Belliss & Morcom

Engines and Air Compressors

When one article or machine is chosen in preference to another, there is generally a carefully worked out reason. Take for example Belliss & Morcom Engines and Air Compressors. They have established definitely and decisively the fact that their users derive from them longer and more efficient service than from other makes. This accounts in a great measure for the "stand in" Belliss & Morcom equipment has with practical engineers, and explains why Belliss & Morcom Engines and Air Compressors are found in many of Canada's most modern engine rooms.

REGISTERED COPPUS U.S.PAT.OFFICE

In Paper Mills

STEADY steam pressure is a vital factor in making good paper. A sudden drop at the gauge might mean serious loss in the mill. Keeping up steam is a matter of prime importance.

That is why modern paper mills are equipping their power plants with COPPUS Turbo Blowers to maintain constant steam pressure under varying conditions of load, fuel, and weather.

For instance, the COPPUS Blowers shown above operating in the plant of the Hampshire Paper Company, makers of good paper, at South Hadley Falls, Mass., have kept steady steam pressure with very satisfactory results. Peak loads are quickly met, steam pressure is always constant, and cheap fuel is economically burned.

COPPUS Turbo Blowers are helping out engineers and speeding up boilers in power plants the country over. Their good work is not confined to the paper industry—it extends wherever power is used and coal is burned. If they are not already working for you it is likely that they could save time, money and labor in YOUR boiler room.

Write for Blower Catalog.

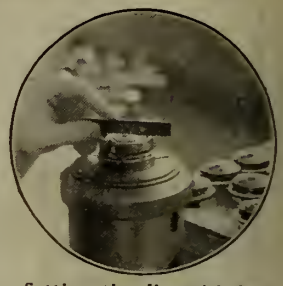
The DUNHAM REG. TRADE-MARK HEATING SERVICE

Every Dunham Trap Is TESTED



Setting the disc with hair-line accuracy. This adjustment is permanent.

Every Dunham Radiator Trap is permanently adjusted at the factory. It never needs attention in service when used within the range of pressure for which it was designed. Dunham Traps are "set by test." Preliminary setting is made with precision tools and gauges to a hair line. Then, **after that,** each individual trap is tested as illustrated to prove that it opens for air and water but closes tight against steam.

There is nothing uncertain, variable or weak about the motive force in a Dunham Radiator Trap. When steam comes into contact with the thermostatic disc, it closes positively with a pressure of 14 pounds against the steam.

There is a Dunham Trap for every need. Full details of all Dunham Specialties will be found in Special Bulletins, covering each of the Dunham Specialties. Write for the one you wish.

AMERICAN-MARSH PUMPS

SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.

American-Marsh Centrifugal pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.

The line also includes—
Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

Why We Say "BUY THAT BOILER NOW"

Read these excerpts from a recent editorial in the Montreal "Daily Star":

"There cannot be ground for serious apprehension even concerning the immediate future of Canada."

"There is no immediate prospect that prices will fall to pre-war levels. Indeed there is a common opinion that in many branches of business the reductions in prices have been excessive and that there will be a recovery to higher figures. Nor is there any such reduction in buying as the pessimists suggest. The volume of retail business is very large and the bulk of the people are purchasing freely. It must be remembered, too, that lower prices will stimulate buying."

"Stocks will be reduced and regular orders to the manufacturers follow."

"Canada has resources such as she never had before. There are hundreds of millions of Dominion bonds in the hands of Canadian holders. The interest goes through Canadian pockets into productive domestic enterprises."

"From November until April the banks and the Government will draw $5,000,000 and thereafter $10,000,000 monthly until the $150,000,000 owing to the Dominion by the Imperial Government is repaid."

"It is true that adverse exchange stimulates purchase of goods in Canada, and thus directly benefits Canadian manufacturers and Canadian labor. Through the rate of exchange we also have an advantage in export over United States manufacturers and producers."

"For 1914 our exports were $431,588,439 and for the last fiscal year $1,289,492,098."

"There is no weakness in the financial situation to create a suspicion of alarm. When the strain of moving the crop has been lessened commercial credits can more easily be maintained and perhaps extended."

"There is a great reserve of purchasing power in the country. The savings deposits in the banks of Canada on October 31st were $1,271,275,751, as compared with $659,806,682 on October 31st, 1914.

"An outward movement of people always follows a war in Europe. To immigration from the Old World will be added a great and continuous overflow from the United States. During the last year 100,000 immigrants entered the Dominion. The Minister of Agriculture for Ontario, who has just returned from Great Britain, believes that in the Spring 10,000 British tenant farmers will come to that province.

"If we are wise and prudent and confident, if we bear with serenity the inevitable penalties of readjustment which no people in the world can escape, and if we will remember that many of us have had a harvest of material gains long and abundant, we will soon emerge without any vital disaster into a new era of progress and prosperity."

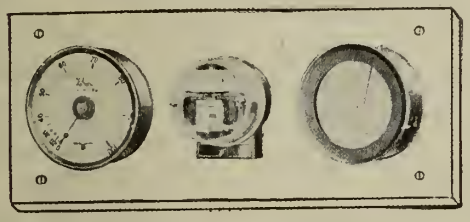
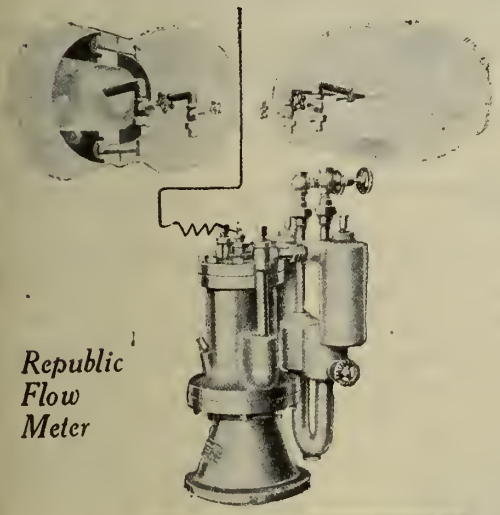
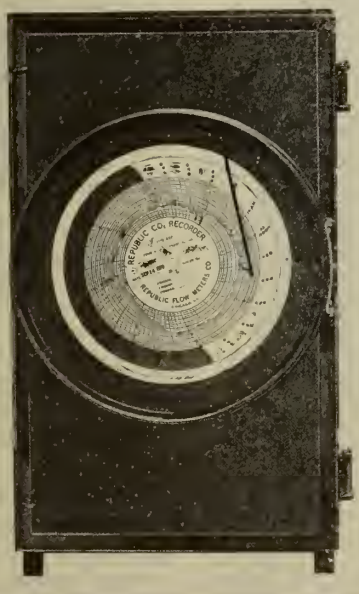
Republic

TWINS A Cost Cutting Combination





Republic Flow Meter



Republic CO_2 Recorder

REPUBLIC FLOW METERS AND CO_2 RECORDERS

Have Become a Vital Necessity in the Economical Operation of Power Plants

AT the present time itemized costs of manufacturing are receiving attention such as they never received before. This being the case, it is essential that every possible means be taken whereby constant and accurate check can be kept on all processes which go to make up the finished product.

Two items which have received little, if any, attention up to the present, are the amount of steam used in the various processes and the amount of steam produced per ton of coal consumed.

You cannot improve your conditions unless you first know what they are.

THE REPUBLIC FLOW METER and CO_2 RECORDER are instruments designed to give you this information and also to keep a constant check on these conditions, the FLOW METERS giving the total amount of steam produced by the boilers, or consumed by the various departments, and the CO_2 RECORDERS giving a record of the combustion conditions in the furnace, and thus showing definitely at all times at what efficiency the fuel has been burned.

The installation of new boilers has been proved unnecessary by the aid of the FLOW METERS, enabling the boiler plant to be maintained at a very much higher efficiency than was possible without their aid.

The CO_2 RECORDERS continuously give a record of combustion conditions, and in this way increase the production of steam per pound of coal to a very large extent.

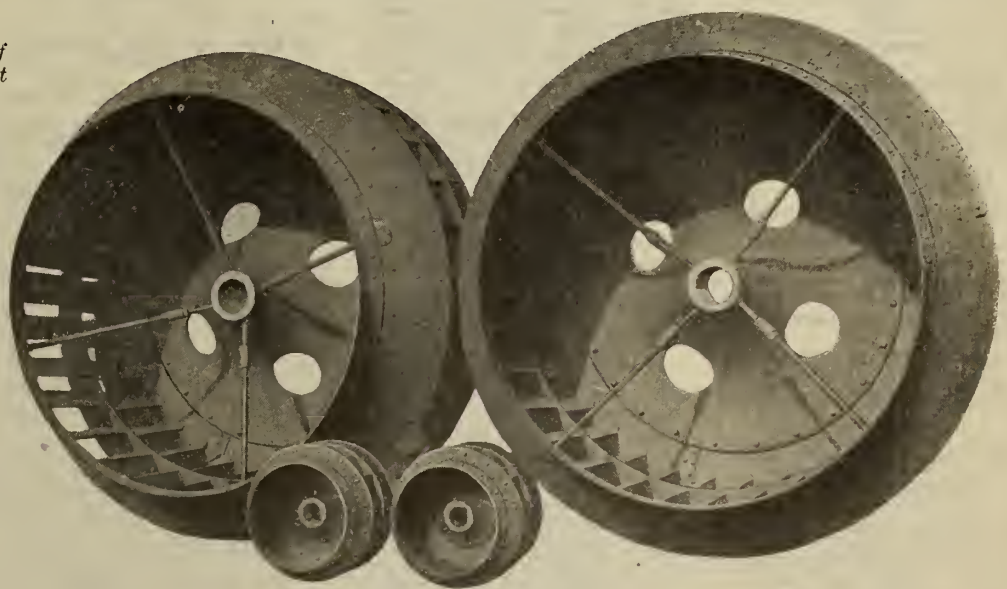
Comparison in Size of the Largest and Smallest Fans Manufactured



More Draft for Less Power

GREEN'S RADIAL FLOW FANS are built for capacities of 1,600 to 275,000 cubic feet per minute and pressures up to 7 in. of water.
These fans, besides having low horsepower requirements, operate at the most economical speeds for direct connection to turbines and motors, making possible small high speed efficient units.
Fans are built in two types—"RB" and "RR"—for forced and induced draft, respectively.
Our Engineers will be glad to submit data covering the requirements of your individual draft problem. Let us send full details.

PUTS AIR TO WORK

Increase Your Generator's Earning Capacity

The first and most important step is to adopt a means by which its load-carrying capacity can be increased. Dust, soot, ashes and oily vapors are the biggest and most expensive hindrances to generators in carrying extra loads. Shutdowns because of worn installations and even burnouts are often the results of allowing these destroyers of efficiency to collect. For that reason an effective generator cooling system must be employed.

Many of the largest power plants, traction companies and other industries of the country have installed STURTEVANT Air Washers for generator cooling and have realized a big saving in time, money and labor. The fact that in one month air washers for 250,000 kw. were sold proves that public opinion of them is favorable. Their installation in the most progressive and modern power plants is inevitable.

Well constructed, and adapted not only for generator cooling, but used extensively for ventilation purposes in big public and commercial buildings and for the removal of smoke, soot and cinders, this air washer has been used most successfully.

For a more detailed description and a clearer idea of the profits and benefits received from this washer, write for our Catalog 226V.

Connelly Water Tube Boilers (Patented U.S. & Canada)

are of the 4-drum type; have 100% tube area in the path of circulation, and deliver steam superheated to from 5 degrees to 10 degrees Fahrenheit. Simple in design, no flat surfaces, no stay bolts, no crown bars, no braces, no handholes, free from joints.

All parts easily accessible for cleaning, both internally and externally. Can be built in units from 200 H.P. up to 4,000 H.P. and 300 lbs. pressure. 150,000 H.P. in successful operation.

86th Year

LEONARD

Could you retire in 20 years?

Perhaps you don't want to—but all the same it is a very pleasant feeling to have enough gilt-edged securities tucked away that if your earnings are cut off you haven't the slightest worry.

A few days ago, there came to our office a merchant from a small Western Ontario town. Perhaps his business was not as big as it might have been, but he was pretty shrewd, for he knew that profit was profit only when you had it safely invested in gilt-edged securities.

For twenty years he had quietly invested his monthly savings, getting his information from the Investors' Enquiry Service of THE FINANCIAL POST. We had noticed his frequent letters, but we never knew just how he used them until he dropped in to see us.

Now his financial worries are over, having sold out and gone to live in sunny California. By following the Investors' Enquiry Service as a subscriber he quietly put away an investment that gave him a sure income sufficient to cover all his needs.

The big point is this—**savings are not savings until safely invested and bearing interest.** There is so much of the average man's earnings that is frittered away in non-essentials, when he might create an estate separate from his business load.

THE FINANCIAL POST points the way to safe, sane investments in sound securities. Through the Investors' Enquiry Service you get the bed-rock facts behind any and all investments. Before you buy—write.

The $5.00 invested in THE FINANCIAL POST service for a year will mean hundreds of dollars to you, if you follow the hints, tips and suggestions in the investment of your profits. When so many have found its pages valuable to them, will you not fill in the coupon and find out for yourself just how valuable THE FINANCIAL POST can be to you?

Even In China
Clean Boilers Mean Greater Profits

Who thinks of China—the "unmoved and unmoving"—in terms of fuel and labor saving devices?

True to tradition ancient Cathay reverencing the customs of the past should calmly ignore the methods and implements of twentieth century "efficiency."

But there is a new spirit in the Oldest of Empires. Machines are replacing hands. Here and there an industrial center is springing up.

And mark you——!

China's manufacturing plants of 1921 are equipped with the best obtainable modern high-speed, high efficiency machinery.

Take Diamond Soot Blowers for example. The installation shown on this page, that of the Yufoong Cotton Mills at Chengchow, Honan Province, is only one of twenty or more installations made during the past year.

With the cheapest labor in the world China is eliminating hand cleaning of boilers. With vast untouched supplies of coal and oil, China is saving fuel through the use of Diamond Soot Blowers.

Even in China clean boilers mean greater profits!

Here, then, is a striking lesson which can well be scanned by every Canadian business man. If Diamond Soot Blowers are a profitable investment in such a land as China, how much more essential and profitable must they be in Canada to-day?

If your boilers are not equipped with Diamond Soot Blowers, and you want to save fuel and labor, write for Bulletin 280.

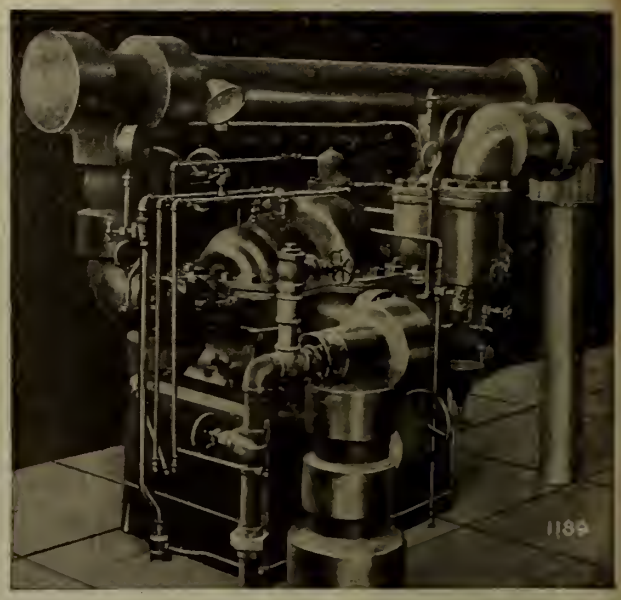
A Boiler Feeder
That Requires Little Space and Attention

The De Laval Combined Steam-turbine-driven Centrifugal Boiler Feed Pump is almost minute in size as compared with reciprocating boiler feeders. It occupies only about one-eighth as much floor space and weighs about one-fifth as much.

It is free from the troubles common to reciprocating boiler feeders. There are no packings, except simple ones about the shaft, no valves, and only two bearings, and these are ring-oiled. All interior parts are accessible upon lifting the casing cover and without disconnecting piping.

The De Laval Boiler Feeder transmits no shock or vibration to the piping. The discharge can be shut off suddenly without excessive pressure or opened wide without racing. The flow is smooth and uniform and ideally adapted for automatic boiler feed regulators and flow meters.

If your plant is of 3,000 boiler horsepower capacity or larger, the De Laval Centrifugal Boiler Feeder is the only pump to consider. Built in all capacities from 3,000 to 60,000 h.p.



Installation of De Laval Turbine-driven Boiler Feeder

Ask for Bulletin N-100.

In Public Buildings

Municipal engineers demand efficiency—and insist on economy of operation. Power plant equipment, to secure the approval of public engineers, must measure up to the highest standards.

This 22″ COPPUS Turbo Blower in the City Hall at Montreal, Canada, has been burning bird's-eye with economy, and holding steady steam pressure without difficulty for many months. Here, as in thousands of plants the world over, COPPUS Blowers burn cheap coal, save time, labor and money, and greatly increase plant efficiency.

That COPPUS Blowers are recognized as leaders in their line is evidenced in the fact that three-fourths of all the blowers made in America bear our trade-mark. Ask our engineers to show you how "COPPUS Equipment can save you money." Write for Blower Catalog.

COPPUS TURBO BLOWER

"I'll back them against any books in the world"

That's what Hal Taylor an all 'round electrician says about these electrical books—the best electrical books in the world. Several thousand other men say the same thing—Master Electricians—Experts in Various Lines of Electrical Industry—Apprentices and Students—they all swear by these great books after comparing them with others.

The WORLD'S GREATEST Electrical Books

8 big books with 4100 pages and 3300 pictures, plans, blueprints and diagrams. Written and prepared by 28 of the best known electrical men in the business. Every word is plain everyday English that anyone can understand. You learn electricity from the ground up with these books—real practical electricity that you can cash in on and earn big money.

8 Volumes Sent for FREE TRIAL

We want every man interested in electricity to examine these wonderful books—to see for himself just what they are. You don't have to put up a cent. We take all the risk and let you have them FREE for a whole week. You can buy them on our easy-payment plan if you want to or send them back at our expense if you like. You be the judge.

Don't Send Money

Don't send us a penny. Merely fill out the coupon and mail it. This will bring you the whole set by express collect to use as you please. After a week's examination you can either return the books at our expense or send us $2.80 as first payment and $3.00 a month until $34.80 is paid. If you return the books in one week you won't owe us a cent.

Mail Coupon Now

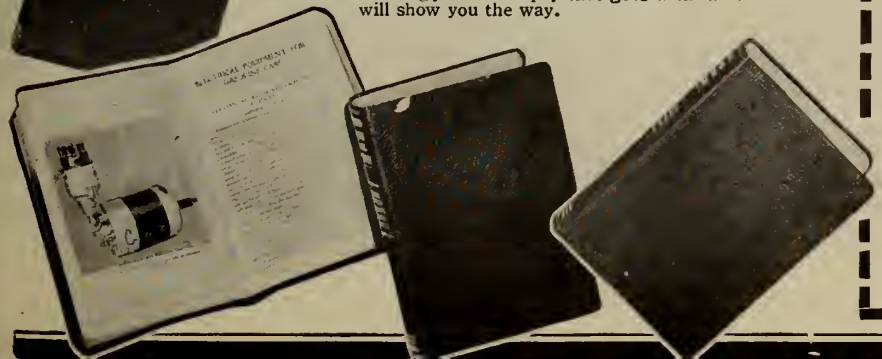
Fill out and mail the coupon today and we will send you a handsomely engraved certificate of membership in this society entitling you to special discounts on instruments and other books and the privilege of consulting our experts by mail on any electrical problems at any time. Don't delay. Mail the coupon at once and get your set of these great books right away for free examination.

YOUR FUTURE IS IN ELECTRICITY

Electricity is the greatest force in the world and it is growing greater every day. The whole world depends on the electrician. Think what opportunities this offers to the fellow with a little ambition. You can succeed in electricity. You can have a big job and the pay that goes with it. These books will show you the way.

Partial List of Contents

Principles of Electricity Telephones; Construction, Operation and Repair Dynamos and Motors; Storage Batteries; Alternating Current Machinery; Switch Boards; Armature Winding; Construction and Operation of Transformers; Electrical Measurements; Electromagnets; Induction Coils, Controllers; Electric Elevators; Railway Signaling; Interior and Exterior Wiring; Materials and Methods used; Underwriters Requirements; Electric Lighting; Planning Systems; Estimating; Contracts; Specifications; Maintenance; Electro-chemistry; Power Stations; Operation and Maintenance; Management of Dynamos and Motors; Electric Welding; Electric Transmission Lines; Distributing Systems; Electric Railways; Construction of Power Plants; New Electrical Devices.



AMERICAN TECHNICAL SOCIETY
Dept. E-1742 Chicago

Please send me a set of Practical Applied Electricity in 8 volumes by express collect, for a week's free use. At the end of a week I will either send the books back at your expense or send you $2.80 as first payment and $3.00 each month thereafter until a total of $34.80 is paid. I understand that I will get a consulting membership in your society, **FREE** with books.

Giant 100 H. P. Semi-Diesel Oil Engine, operating A. C. Generator. Parker City Lighting Company, Parker City S. D.

Simplicity insures continuous operation— easy starting—low attendant costs

THE unique *simplicity* of Giant Semi-Diesel Oil Engines particularly adapts them to electric generating service, especially in isolated or municipal plants where conditions are unusually severe and highly trained attendants both scarce and expensive.

This feature of Giant Oil Engines has popularized them with power users in almost every industry. Giants are readily started from a cold condition. Quick, positive starting is insured by the Hot-Liner method—the most perfect ignition system yet developed for oil burning engines. Operation, once started, is entirely automatic.

A saving in maintenance, equally as important as fuel economy, is effected by Giant simplicity. There are no carburetors, magnetos, valves, complicated mechanisms or costly auxiliaries to lessen dependability or increase upkeep costs.

Get down to *"brass tacks."* Learn how much a Giant Oil Engine can reduce your monthly power bills. Engineering service, extended without obligation, will aid you in determining power-bill savings that frequently return the initial cost of a Giant installation in a short time.

Giant Oil Engines are built in capacities from 12 to 200 H. P., single and duplex types. Bulletin 389 contains descriptive details.

What Lubricants Do You Use?

PROPER plant lubrication is important. The selection of lubricants merits careful consideration. The reputation of Imperial Lubricants has been honestly earned by the many years of satisfaction rendered to Canada's more important industries.

Insist on a lubricant with the Imperial brand. Make sure that you are using the right grade and you will cut lubrication costs, reduce repair and upkeep expenses and increase the output of your plant.

The question is, not how many gallons, but it is, *how much lubrication* you get for your dollar. Poor lubricants are expensive at any price. Imperial Lubricants are carefully formulated and are always of uniform high quality.

You will find a lubricant exactly suited to every bearing and every unit in your plant in the list at the right. Standardize on Imperial Lubricants. Supplies always conveniently available.

Imperial Lubrication Engineers will gladly advise with you regarding any lubrication problem. Write to 56 Church St., Toronto.

A REAL GUARANTEE

A guarantee can be worded so as to mean a great deal—or nothing at all. With us, the *spirit,* not the letter of the guarantee, is the vital thing. Briefly, *we guarantee satisfaction to every customer.*

A complaint has never come to our attention that we have not handled promptly and in a manner entirely satisfactory to our customer. We have been in business since 1844. This means that we have rendered satisfactory service in the past. We intend to remain in business for many years to come, which means that we must keep on giving satisfaction.

Only to *satisfy* a customer does not fully meet our conception of service. We aim to give him such a full measure that it becomes a *pleasure* for him to do business with us.

This Mark On Belting

STANDS FOR

D. K. McLAREN'S

BRITISH-OAK-TANNED
FLAWLESS BACK LEATHER

EVERY D. K. McLaren Belt has the Oak Leaf stamped plainly upon it.

For many years this mark has been a guide to efficient, economical belt service for many of Canada's prominent industrial power plants.

Let it guide you, as it is guiding others, to satisfactory belting service.

Just fill out the coupon below and we gladly help you find out what users think of D. K. McLaren's Belting. We'd like you to profit by the experience of others.

Back Leathers—This is the best portion of the hide for belting purposes. Every inch of D. K. McLaren Belts represents Flawless Backs of the hides of the choicest steers.

British-Oak-Tanned—The most approved process known for preparing belts for hard service. Every bit of the hide's natural strength is preserved in D. K. McLaren's Belts by the expert use of this famous process.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

CUT YOUR PRODUCTION COSTS

After five years of unequalled industrial activity comes a breathing spell that provides the opportunity for long-deferred repairs and improvements that will enable you to *cut your production costs in the future.*

At one plant where Riley Underfeed Stokers were recently installed, six boilers equipped with Rileys easily carry the load that ten boilers with another type could scarcely meet.

Not only this but a cheaper grade of coal is being burned with a saving of 25 to 30% in amount of fuel used.

Consider carefully what such savings would mean in your plant and you will decide that *now* is the time to investigate and install Riley Underfeed Stokers.

Let us send you our Catalog HR-3.

For information on the Murphy Automatic Furnace for small plants, see last month's advertisement, or send for Murphy catalog HM-2.

You'll Know It By The Diamond Trade Mark

Dependable performance is guaranteed the buyer of Diamond Trade Marked Valves.

The name "Jenkins" within a Diamond Mark cast on the valve body—every **genuine** Jenkins valve carries it, a protection to the customer against inferior imitations.

And whatever the service, whether for steam, water, oil, air, gas or chemicals, genuine Jenkins Valves will prove safe and dependable.

Jenkins Valves are made to serve. They are designed throughout for the **maximum** service, not merely the average—and tested in this regard before leaving the factory.

Supply houses everywhere carry a complete stock of Jenkins Diamond Trade Marked Valves. Catalog No. 8 (free on request) will show you how comprehensive the Jenkins line is—a valve for every purpose.

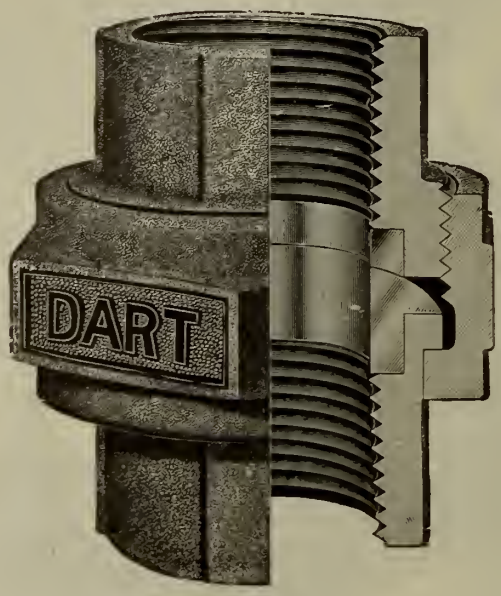
DART UNION PIPE COUPLINGS STAY TIGHT

Dart Unions

Make a joint that is proof against deterioration. A joint that will never loosen up and leak.

Their permanent efficiency is due to the non-corrosive Bronze Face and Seat and the Heavy Malleable Iron Pipe Ends and Nut which will not stretch or pull apart under heavy pressure or strain.

They ensure a Leak-Proof Service which leaves no loopholes for complaints.



Dart Unions

Pipe lines are easily connected up, thus effecting a "first cost" saving. They are there to stay until deliberately loosened with a wrench.

The Face and Seat being ball-shaped permits easy and perfect connection even if pipes are out of alignment.

Dart Unions always satisfy. Specify Dart Union pipe couplings in your next jobbers' order.

Another Call for Mason Service!

Mason No. 55
Pump Pressure
Regulator

Mason Standard
Bronze Reducing
Valve

Why--

Mason Service and Mason Appliances are in continual demand to-day by Power Users everywhere. Whether it be pressure regulation, engine or pump control, damper or blower regulation, or condensation drainage or returns, there is a Mason apparatus to handle it. And the thousands of Mason devices giving more than satisfactory service in critical positions is a silent testimony to the thoroughness of Mason design and construction.

No other devices work so accurately, wear so long nor accomplish their purposes so fully as the Mason. Once installed they require little attention and always bring "repeat orders."

This is aided by Mason Service—a service constituting a staff of expert engineers, each a specialist in the application of certain of our devices. It is their duty to aid and advise the most economical equipment compatible with efficiency.

We handle Valves and Regulators for every purpose. Engineers and Power Users are heartily invited to discuss their problems with us. If there is a solution we can solve it.

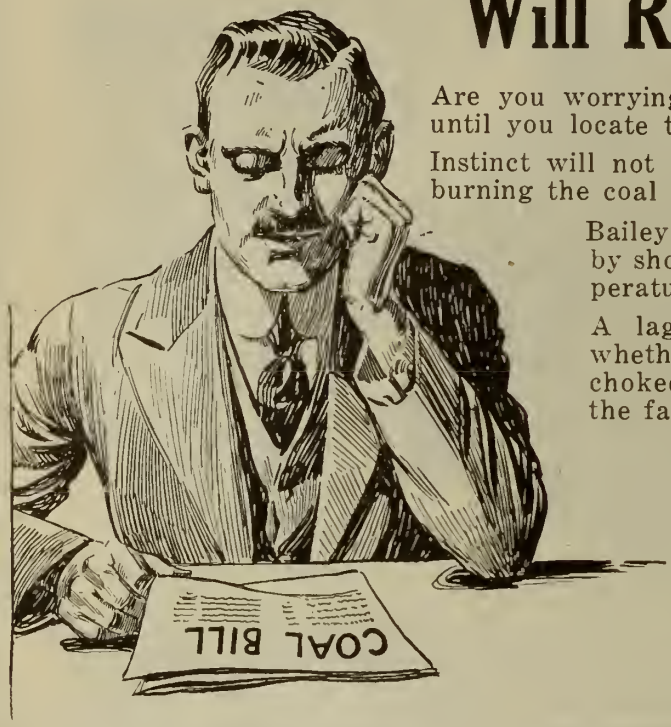
Bailey Boiler Meters
Will Remove That Worry



Are you worrying over coal leaks? You can't eliminate them until you locate them.

Instinct will not tell your fireman just how well each boiler is burning the coal fed to it. The best they can do is **guess.**

Bailey Boiler Meters will enable them to **know exactly** by showing the steam flow, air flow and flue gas temperature—on the one chart.

A lagging boiler is shown up. The meter tells whether excess air, fouled tubes, broken baffling or choked fires is the cause. There is no guesswork—the facts are right before them all the time.

Write for bulletin.

Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the Celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

Make Your Baffles Gas and Air-Tight and Reduce Fuel Bills

Views above illustrate how easy it is to install baffles with

PLIBRICO JOINTLESS FURNACE LINING

PLIBRICO makes one-piece baffles, having NO joints, which ARE gas-tight and which remain so. PLIBRICO baffles last longer and give better service.

No tiles or blocks to break up, crumble or be dislodged and it is an impossibility for valuable gases to short circuit. Not affected by expansion or contraction.

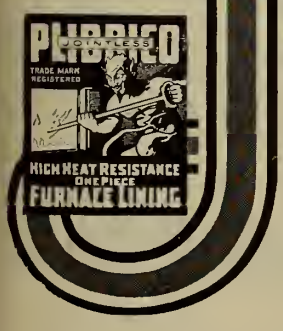
Forms and special tools unnecessary. Any man can apply it.

Try PLIBRICO baffles on one boiler and you will standardize on PLIBRICO on all your boilers, as so many other plants have done. The first installation will quickly prove its great fuel-saving feature.

PLIBRICO is a plastic, easily applied, monolithic furnace lining that may be used to patch up old boiler settings or to put in new settings that last three times as long as ordinary fire brick.

PLIBRICO is delivered only in steel containers of distinctive appearance as shown below. Immediate deliveries from warehouse stocks in principal cities.

Write for book on Furnace Building. Contains valuable diagrams showing modern settings for all types of boilers.



JOINTLESS FIRE BRICK CO.

1130-1150 CLAY ST. CHICAGO.

Buy Your Boiler Now—

With easier money rates and reduced retail stocks the country over, a genuine business revival is just around the corner. We can give that new boiler order good service now.

GREEN'S

HI-EFFICIENCY HI-SPEED

RADIAL FLOW FANS

All parts of Green's Radial Flow Fans are easily accessible. Their power consumption is exceedingly low and their sturdy construction assures long wearing qualities.

These are but a few of the many features which recommend Green's fans to careful buyers. Write for our new booklet No. 152; it contains detailed information.

Consult our engineers. They will gladly furnish you complete information with regard to fans to cover your individual requirements.

GREEN'S ECONOMISER, LIMITED.

TORONTO

Republic
CO_2 RECORDERS

Meters that SHOW Where Your Dollars Go

In the Republic the analysis is recorded by a continuous line on the chart. The case complete measures 22x12x5 inches and the entire instrument weighs only 45 pounds.

How Much Coal Did You Burn To-Day?

Do YOU know? And supposing you have an approximate idea of the total fuel consumption, do you know how much of that coal is actually generating power-producing heat? For if combustion is not taking place properly much of that coal which costs so much is going up the smoke stack in gases and heat—utterly useless for power purposes.

You who are so careful in other matters of business—can you afford to go on burning coal regardlessly? Especially when a small sum invested in a Republic CO_2 Recorder will eliminate all waste and put you on the road to **greater fuel economy.**

The Republic CO_2 Recorder is a simple, remarkably accurate apparatus for analyzing flue gases. No other Recorder is so compact and requires so little attention. The Republic CO_2 Recorder has no glass, no delicate parts, nothing to go wrong.

A good CO_2 Recorder is a wise investment. A Republic is your best investment because it saves most. Write for bulletin.

Jones

Results That Can Be Duplicated In Your Plant

Note How Jones "A-C" Stokers Met the Unusual Conditions of this Canadian Plant

The boiler test (opposite) tells more clearly than any amount of description, how efficiently and economically Jones Stokers are meeting the firing requirements of the Fort Frances, Ontario, plant of the Minnesota and Ontario Pulp and Paper Company.

Results like these (they are being duplicated in many Jones equipped plants) emphasize two outstanding advantages of all Jones installations:

(1) The inherent advantages of Jones design.
(2) The engineering service that is a part of every installation.

The basis of the high efficiency of Jones Stokers is the Under-feed principle of combustion, a *Jones* principle, originated and perfected in Jones Stokers.

Heavy Overloads—No Reduction of Efficiency

The fuel, fed by the steam operated ram, is moved mechanically through the long retorts by means of the pusher rods. During its slow travel hydro-carbons are entirely volatilized and completely burned. So the same high combustion efficiency is maintained at high combustion rates as when lighter loads are carried. This is evidenced by the extremely low combustible in the ash even when heavy overloads are carried. The under-feed principle is particularly adapted to burning Canadian coal. Added to the basic advantage of the under-feed principle are:

—*Simplicity,* insuring low maintenance.
—*Automatic control of fuel and air,* insuring even steam pressure regardless of load fluctuations.
—*Automatic-Cleaning,* (in the "A-C" type).
—*Individual control of retorts,* insuring an even fire and high efficiency—and many other distinctive features that adapt the Jones Stoker to every load and every Canadian coal.

Special Firing Problems Solved

Just as Jones engineers met the unusual conditions presented by the Fort Frances Mill where coal and "hog" fuel are burned in combination, they will solve *your* problem—whether a load problem, fuel problem, or labor problem. The engineering service, outlined opposite, is at your command. A survey of your plant implies no obligation.

Few catalogs tell the story of Jones superiority.

Jones Stokers made in two main types: Jones "A-C" (Automatic-Cleaning) high-duty type, and Jones "Standard". Jones engineers will advise which type is best suited to local conditions.

100% Canadian

Jones Stokers are made in Canada by Canadians and sold for Canadian money at par. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been reorganized and, although the experience and facilities of the older organization are retained, the reorganization also makes available for Canadian power users the extensive engineering resources of the Under-Feed Stoker Co. of America.

REES RoTURBo PUMP

Recently installed for Fire Service at the Stratford Waterworks Pumping Station.

Previous to this installation the Stratford Waterworks was equipped with several different makes of Centrifugal Pumps, among them a Rees RoTURBo; it was because of the excellent performance of this pump installed some years ago that the REES was again chosen when additional equipment was required. Rees Pumps are dependable, and their self-regulating, wear-resisting construction make for permanently and highly efficient service over a wide range of duties. A Series of Articles on Power Plant Management

In This Article the Various Makes of Turbine are Described, Their Operating Features and Comparative Points of Vantage Being Indicated.

By ROBERT JUNE

IT is not a very satisfactory proceeding to attempt a general classification of steam turbines because the various groups overlap to a considerable extent. However, there are sufficient differences in the characteristics of a number of well known turbines so that they may be conveniently classified according to the fundamental principles involved in their operation, as follows:

Impulse				Reaction	Combined Impulse & Reaction
Single Velocity	Multi-Velocity Stage	Single Velocity Stage	Multi-Velocity Stage	Multi-Velocity Stage	Multi-Velocity Stage
De Laval	Terry Sturtevant Curtis (small type) Westinghouse	Kerr De Laval Rateau	Curtis	Westinghouse-Parsons Allis-Chalmers-Parsons	Westinghouse
Single Pressure Stage		Multi-Pressure Stage.			

Impulse Turbines

In turbines of the impulse type the complete expansion takes place in the stationary blades or nozzles and the steam is delivered to the moving blades with a velocity somewhat more than double that of the blades. The velocity of the jet is very high, from 2,000 to 4,000 feet per second, and for satisfactory economy the peripheral velocity of the wheel must also be very high. The passages between the moving blades are of uniform or even slightly increasing cross section from inlet to outlet. The moving blades check and reverse the velocity of the steam current, thus creating a force against the blades which sets the rotor in motion.

If the entire pressure drop takes place in one set of nozzles and the resulting jet is directed against a single wheel, the turbine is classified as belonging to the single stage, single velocity group, of which the DeLaval Class "A" turbine is a well known example.

We have just stated that for satisfactory economy the peripheral velocity of the wheel must be very high in turbines of this sort. However, it is possible to use a lower speed rotor by compounding the velocity. When this is done the jet issuing from the nozzle at a very high velocity is reflected back and forth from the vanes on the rotor to a series of fixed reversing buckets until all the available kinetic energy of the jet has been imparted to the wheel. An excellent illustration of this type of turbine is the Terry single stage machine.

Other means of combining low peripheral velocity and high expansion takes place in a series of successive nozzles instead of one nozzle. Thus, only a fraction of the available heat energy is converted into kinetic energy in each nozzle. For each set of fixed nozzles there is a corresponding rotor. To all intents and purposes this type of turbine consists of a series of single velocity impulse turbines placed side by side.

If we compound both velocity and pressure we have the multivelocity and pressure type of which the Curtis turbine is the best known example.

Reaction Type Turbine

In the reaction turbine, approximately one-half of the expansion in any one stage takes place in the stationary blades, imparting to the steam a velocity substantially equal to that of the moving blades so that it enters them without impulse. The remainder of the expansion takes place in the moving blades, the spaces between which gradually grow smaller from inlet to the exit side of the turbine, thus forming a ring of moving nozzles. The velocity imparted to the steam by reason of the expansion occurring in the moving produces a reactive force on these blades which turns the rotor of the turbine.

Only a very small portion of the heat energy imparts velocity in the first set of fixed blades or nozzles. As the expansion is very gradual a large number of alternate fixed and revolving blades are necessary to effect complete expansion.

Combined Impulse and Reaction Turbines

In multi-stage work it has been found that the use of an impulse element for the first stage of expansion and the use of reaction elements for the subsequent stages forms an effective combination. The impulse element replaces without

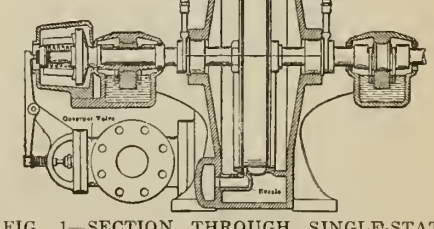

FIG. 1—SECTION THROUGH SINGLE-STATE TERRY STEAM TURBINE.

any appreciable sacrifice of economy a considerable number of rows of reaction blades in the least efficient part of the reaction turbine, and makes possible a shorter, and consequently, stiffer rotor. The Westinghouse-Parsons double

flow high pressure turbine is typical of this class.

Respective Advantages of Impulse and Reaction Turbines

The impulse and the reaction turbines represent two schools of engineering development, each of which secures practically the same result as the other, but by slightly different means. It is fully as difficult to compare the advantages of one type of turbine over the other as it is to compare the respective advantages of horizontal and vertical water tube boilers. While many engineers can offer excellent reason for preferring one type of turbine over the other, the fact remains that to a great majority of engineers these reasons are comparatively unimportant, and their preferences will depend not upon general considerations, but upon the conditions obtaining in their individual plants.

It is plain that in the impulse type, because of the considerable difference in pressure which exists between adjacent stages and the fact that steam leakage increases as the square of the pressure drops, that it is very important that means be devised to minimize the leakage and resultant loss of efficiency. It has, therefore, been the universal practice with this type of turbine to employ a rotor built up of disks mounted on a shaft of small diameter in order that the clearance between the shaft and the diaphragm separating the pressure chambers may be as small as possible. This construction results in a ligh' shaft which may develop deflection seriously. It is also claimed that the disks of the impulse turbine are subject to frequent temperature changes, and because of these changes and the high velocities at which the turbine operates, the disks are to some degree liable to rupture.

An advantage claimed for the impulse turbine is that because the blades are very much larger and very much fewer in number than the reaction blades, that there is considerably less difficulty in maintaining them.

For the reaction turbine it is claimed that the rotor, being made up of a comparatively thin cylindrical drum of considerable diameter with rings of large bore, that the internal strain in the disks is negligible. It has also been said that the drum construction of the rotor makes the reaction turbine very much more accessible for examination and repair.

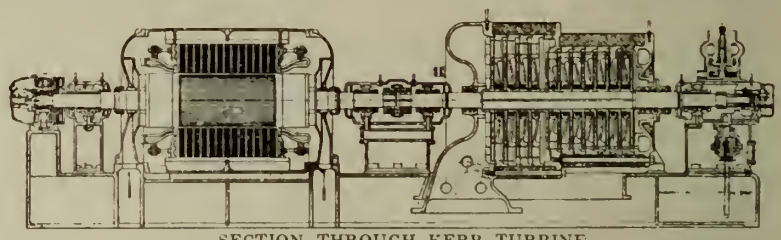
It is well to remember, however, that the several types of turbines are made by concerns of the very highest standing in the engineering world, and this fact may be practically considered as a guarantee of the successful operation of the turbines produced by these manufacturers.

Terry Non-Condensing Turbine

In the Terry non-condensing turbine, Fig.1, courtesy Gebhardt, the compounding the velocity permits of much lower peripheral velocities than with the single-velocity type. The rotor, a single wheel consisting of two steel disks held together by bolts over a steel centre, is fited at its periphery with pressed-steel buckets of semi-circular cross section. The inner surface of the casing is fitted with a series of gun metal reversing buckets arranged in groups, each group being supplied with a separate nozzle. The steam issuing from nozzle N at very high velocity strikes one of the buckets on the wheel, and since the velocity of the buckets is comparatively low, is reversed in direction and directed into the first one of the reversing chambers. The chamber redirects the jet against the wheel, from which it is again deflected; this is repeated four or more times until the available energy has been absorbed by the rotor. Terry turbines are made in a number of sizes varying from 5 to 800 horse power, and operate at speeds varying from 210 feet per second in the smaller machine to 260 feet per second in the larger.

Kerr Turbine

The Kerr turbine, Fig. 2, is of unusual design in that it is built up in sections, the casing comprising a steam end, exhaust end, and whatever number of intermediate stages are best suited to meet the individual condition. The rotor consists of a series of steel disks, mounted on a rigid steel shaft. A series of drog-forged steel buckets is secured to the periphery and riveted in dovetailed slots. The tips of the buckets are riveted to a shroud ring, thereby insuring a rigid and positive spaced construction. The stator is made up of a number of arched cast-iron diaphragms with circular rims tongued and grooved, and bolted to steam-end and exhaust-end castings.



SECTION THROUGH KERR TURBINE.

The operation is as follows: Steam enters the turbine through a double-beat balanced poppet valve, the stem of which is connected through levers to the governor, to the circular cored space extending around the steam "end casting." This space acts as an equalizer and insures uniform admission to the first set of nozzles. Partial expansion takes place through the first set of nozzles and the kinetic energy is imparted to the rotor through the medium of the vanes. Steam leaves the buckets at a very low velocity and is again expanded through the second set of nozzles in the diaphragm. This process is repeated in each stage.

Westinghouse Turbine

In the Westinghouse impulse and reaction turbine, single-flow type, Fig. 3, the substitution of the impulse element for the high-pressure section of reaction blading has essentially no influence on the net efficiency of the turbine. That is to say the efficiency of the impulse wheel is about the same as the least efficient section of reaction blading. This design is attractive, however, in that under some conditions it shortens the machine and gives a stiffer design of rotor.

The entering steam is confined in the nozzle chamber until its pressure and temperature have been materially reduced by expanding through the nozzles. As the nozzle chamber is cast separately from the main cylinder, the temperature and pressure differences to which the cylinder is subjected are correspondingly lessened.

Westinghouse Double-Flow Turbine

The maximum economical capacity of a single-flow turbine is limited by the rotative speed. The economical velocity at which the steam may pass through the blades of the turbine depends on the velocity of the moving blades. The capacity of the turbine depends on the weight of the steam passed per unit of time, which in turn depends on the mean velocity and the height of the blades. For a given rotative speed, the mean diameter of blade ring practicable

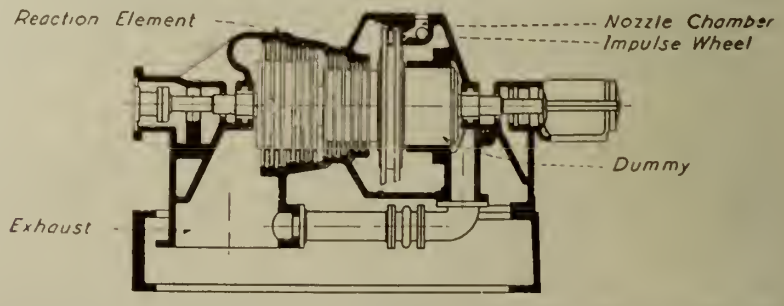


FIG. 3—SECTION OF A COMBINATION IMPULSE AND REACTION SINGLE-FLOW TURBINE.

is limited by the allowable stresses due to centrifugal force, and there is a practical limit for the height of the blades.

Now, if we make the rotative speed only half as great, the maximum diameter of the rotor may be doubled and, without increasing the height of the blades, the capacity of the turbine will be doubled. So with the single-flow steam turbine as well as with the single-crank reciprocating engine, there is a practical limiting economical capacity for any given speed. If this limit is reached with a single-crank reciprocating engine, we may produce a unit of double the power at the same speed by coupling two single-crank engines to one shaft.

The Westinghouse double-flow turbine is in effect, as will be seen from Fig. 4, two single-flow turbines made up in a single rotor in a single casing with a common inlet and two exhausts. Steam enters the nozzle chamber, acts on the impulse element, and then the current divides, one-half of the steam going through the reaction blading at the left of the impulse wheel; the remainder passes over the top of the impulse wheel and through the impulse blading at the right.

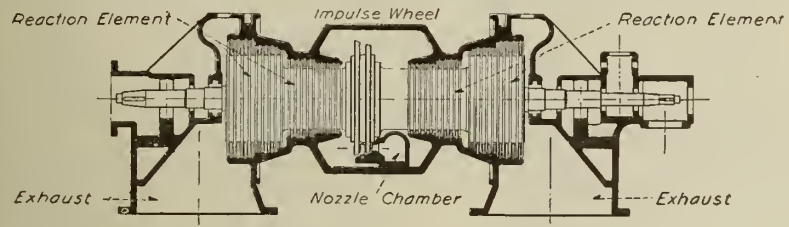

FIG. 4—SECTION OF A DOUBLE-FLOW TURBINE.

Curtis Turbine

All General Electric Curtis turbines, ranging from the very small direct current machines to the huge turbo-alternator of 45,000 k.w., are of the impulse type. So many changes are made in these, as well as in other turbines from year to year, that descriptions can only be given in the most general terms.

In practically all sizes the high-pressure stage comprises a set of nozzles and a single wheel carrying two rows of buckets. Subsequent stages have but one row of buckets on a single wheel, except in the low pressure element of the compound cylinder units where there are two wheels per stage, each with a single row of buckets. The steam flow is axial in all machines.

The speed of the smaller machines is controlled by a centrifugal governor, mounted on the end of the main shaft, which actuates a throttling valve of the balanced poppet valve type.

A relay governor of the hydraulic type controls the large turbo-alternators. Oil is fed to a cylinder under pressure through a pilot valve under control of the main governor. The piston rod of the cylinder contains a rack which meshes with the pinion on a camshaft which in turn lifts the individual control valves as determined by the spacing of the cams.

Bleeder Type Turbine

One of the most interesting developments of the steam turbine is the so-called bleeder or extraction type. Steam is automatically bled from an intermediate stage for heating or manufacturing purposes after it has passed through and done work in the high pressure stages of the turbine. Steam is usually bled at from one to fifteen pounds pressure in quantities from a minimum amount up to throttle capacity of the turbine.

FIG. 5—1000 K.W., 60-CYCLE CURTIS STEAM TURBINE WITH AUTOMATIC STEAM EXTRACTION DEVICE.

It is probably due to the demands of the textile industry more than any other that this type of turbine was developed. The steam so bled is absolutely free from oil and may be used for dye vats, bleaching, slashing, etc., without danger of injury to the product. In conclusion, it has been possible here to describe in rather general terms the principles of operation and the details of construction by which the various turbines differ from each other. For a discussion of the advantages and disadvantages of steam turbines, reference should be made to part 1 of this article, published last month. It seems well in closing to emphasize the fact once more that builders of turbines generally occupy a very high position in the engineering field, and that entire dependence can, as a general proposition, be placed upon the statements and recommendations of the various makers.

OVERCOMING THE HIGH CHARGES FOR HEATING

The annual coal consumption in Canada for domestic purposes is nearly 7,000,000 tons which, if we allow a cost of $15 per ton, represents a yearly expenditure of some $105,000,000. With increasing population and the gradual extension of settlement northerly, this consumption will naturally increase; any effort, therefore, having for its object a substantial reduction in our domestic heating bill, is worthy of public attention.

The hope of relief, entertained by some, through electric heating from our water-powers, has been definitely shattered by the fact that, outside of the question of cost, the demand would far exceed the supply available. For instance, in Quebec and Ontario, alone, assuming a population of some 5,000,000, a total of probably not less than 10,000,000 h.p.—and costing from $150,000,000 to $200,000,000 per annum—would be required to supply electrical heat. The power available within the more thickly populated portion of these two provinces, even including Canada's equity in the great possibilities of the St. Lawrence and Niagara rivers—the greatest water-power rivers in the world—only amounts to about 5½ million horse power.

The possibilities and economic efficiency of central heating plants appear particularly applicable to Canadian conditions or to any country with long winters. Due to the initial cost of the underground distribution piping system, the plants usually involve heavy overhead expenses; when the plant is used intensively and during long periods each year, the charges can be spread over longer periods than would be the case for systems only used during shorter periods, as in certain localities in the United States. Another economy would result from the possibility of using the cheaper grades of coal, instead of the expensive anthracite now commonly used in Eastern Canada. Suitable boilers with automatic stokers and smoke-consumers would overcome some of the present disabilities in the use of the inferior fuels.

—L. G. Denis.

A Disastrous Fly Wheel Explosion

NOT long ago one man was killed and two others were injured by being struck by fragments from a flywheel which exploded in a sawmill and hardwood-floor factory. The engine was of the Corliss type and was belted to an electric generator which supplied current for operating the machines in the factory. The flywheel was 18 feet in diameter, with a face about 36 inches wide, and was operated at a speed of about 92 revolutions per minute.

THE DAMAGED ROOF OF THE FLOORING FACTORY.

The accident occurred soon after starting-up time in the morning. The engine-room was totally wrecked, and bricks and pieces of broken flywheel were thrown in all directions. One of the spokes of the flywheel was thrown into the air and came down through the roof of the sawmill about 150 feet distant. It struck a man who was working there and killed him instantly.

A large piece of the rim crashed through the roof of the flooring factory near by, struck an edger table, and tipped over upon the concrete floor. Three workmen were close by the machine at the time, but fortunately escaped injury. Still another large fragment was thrown into the air and after travelling several hundred feet buried itself deep in the ground. The illustrations herewith will give some idea of the conditions after the accident.

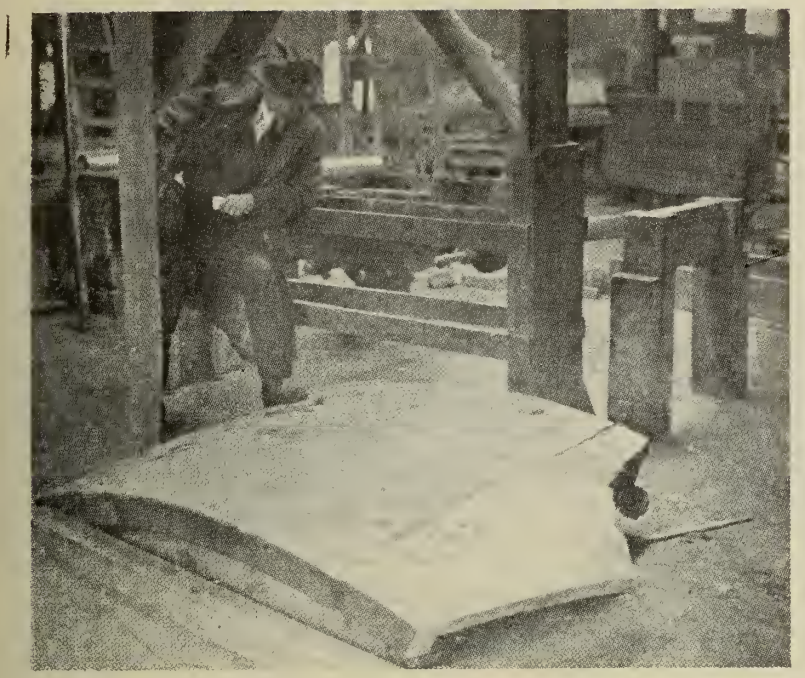
The extensive property damage which resulted from this explosion, and the distance to which large sections of the burst flywheel were carried, appear to indicate that the wheel burst from overspeed. We do not know what cause, if any, has been assigned for the failure of this particular wheel, but it may be interesting and profitable to discuss the bursting of flywheels in general, in order to direct attention to some essential features of safe engine-operation.

One of the commonest causes of flywheel explosions that occur in consequence of overspeeding is the failure of the governing apparatus. In the case of a belt-driven governor the belt may break or slip, or come off the pulley on which it runs, or the key or set-screw which secures this pulley to the shaft may work loose or drop out. If any of these things should happen the governor would become inoperative and the engine would be likely to run away. A similar result might follow the disarrangement of the mechanism of a shaft-driven governor or of a governor of the centrifugal type.

It is vitally important, therefore, to inspect the entire governing mechanism frequently and thoroughly, and to make sure that it is in good working order at all times. The belts of belt-driven governors should be kept at the proper tension and free from oil and grease, which would cause them to slip. The key or set-screw that secures the governor pulley to its shaft should be kept tight, and the gears of gear-driven governors should be kept well lubricated and in good condition in every other respect.

For greater security, a governor safety-stop should be provided in connection with each fly-ball governor. This may be operated electrically or mechanically, and should be arranged so that when the governor rod descends to a dangerously low position (in consequence, for example, of the breaking of the governor belt), a spring or some other equivalent device will be released, which will close the steam-admission valve and stop the engine. A safety-device of another form consists in an idler pulley, which rests on the governor

THE REMAINS OF THE FLYWHEEL.



A SECTION OF THE BROKEN FLYWHEEL RIM.

belt under ordinary circumstances, and is connected to a quick-closing valve in such a way that the steam will be shut off if the belt breaks and allows the idler pulley to drop.

In connection with machines (such as large engines), which are capable of producing so much harm in case anything goes wrong, it is desirable to take every reasonable precaution to prevent accidents. It is therefore advisable to provide, in addition to the ordinary governor, an automatic speed-limiting device which is designed to limit the speed of the engine independently of the governor. A number of different devices of this kind are available, which are of proved value. Some of them are more or less complicated in design and construction and require careful mechanical adjustment, and some of them are operated electrically. Every such device should receive proper care, and the instructions of the manufacturers with regard to installation and maintenance should be rigidly followed. It should also be tested frequently and regularly, and the character of the tests should be such as to leave no doubt with regard to the positive and effective operation of the entire apparatus.

Other possible causes of overspeeding in connection with accidents such as the one under discussion are the breaking of the main driving belt and the sudden removal of the load on the engine due to failure of the electric generator that the engine is driving. In either case the prompt and effective action of the governing and controlling devices must be depended on to prevent disaster.

There appears to be an unfortunate tendency on the part of many persons to place too much reliance on automatic safety devices and to feel that the mere installation of them is sufficient to secure all the benefits and advantages that such apparatus is intended to provide. These persons are likely to become careless in performing certain duties that are absolutely essential for safety in the absence of automatic devices, and to either carry these duties out perfunctorily or to omit them altogether. Eventual disaster may reasonably be expected if this state of mind is allowed to persist, because any mechanical or electrical device, however nearly perfect it may be, may fail to operate at a critical time, through no fault of the designer or manufacturer of it. Even though material safeguards of the most approved type are in place, personal vigilance should never be relaxed for a moment, nor should any precaution ever be omitted which tends to insure the safety of life or property.

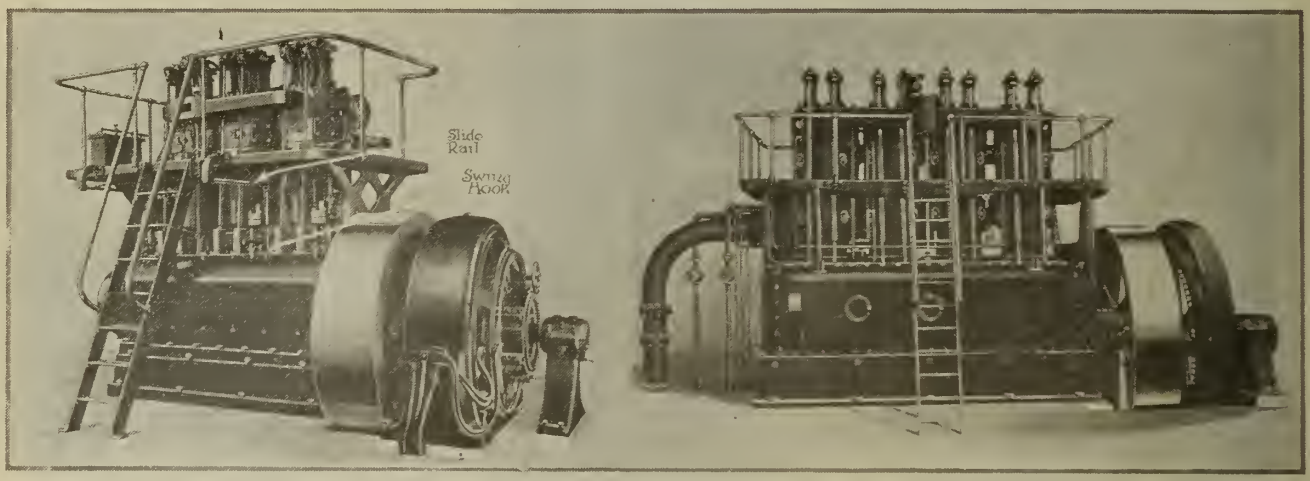
MOLYBDENUM IN STEEL MAKING

A prominent American metallurgist states that ferromolybdenum is added in a fixed condition. It is supposed to give the steel properties similar to those of tungsten steel, but only one-third to one-half as much molybdenum is necessary; that where regular, high-speed steel contains 18 per cent. tungsten, 6 to 9 per cent. of molybdenum may be substituted. However, it gives these properties only when the addition is properly made and proper heat treatment follows. The regulation of these factors caused so much trouble and expense that, in the United States, the manufacture of molybdenum high-speed tool steels has been practically discontinued for several years. It is used for this purpose in other countries, however, to a considerable extent. At the present time it is mainly employed in tool steel as an auxiliary rather than as a major constituent. Various reasons have been assigned for the discontinuance of the use of molybdenum.

An experiment in paving is being carried out on the Victoria Bridge across the St. Lawrence at Montreal, and if the method of paving is successful, the entire length of the bridge will be completed next year. Two hundred feet of mastic flooring are being laid, with the object of determining how well it will withstand the weather during the winter. One advantage claimed for the material is that it is fireproof, and will prevent such disasters as the starting of fires caused by the overheating of gasoline and oil from passing automobiles.

GENERAL VIEW OF WRECKED ENGINE ROOM.

A New Development of the Heavy Oil Engine



By F. A. McLean, Canadian Ingersoll-Rand Co.

FOR power plant service the advantages obtainable from the use of oil engines are briefly: simplification of equipment, a reduction in labor charges, the elimination of standby losses, a saving of space—due to the absence of boilers and accessory equipment—and a simpler and more convenient fuelling problem, representing in their entirety a much lower cost for power output.

Plant owners and engineers have paid close attention to the story of oil engine development, which within the last few years has been one of gradual transition from the Stuart or Diesel type, with its well-known high fuel economy, but poor flexibility in starting and stopping, and necessity for operating on high temperatures and at high pressures, with consequent trouble, due to the inability of the metals obtainable to stand the severity of the service.

Following this came the development of the so-called Semi-Diesel type, which eliminated some of the complications of the earlier type, but introduced others that are equally undesirable. In comparison with the Diesel type it has a much lower operating economy; consumes more lubricating oil; is difficult to start, and requires the use of a blow torch for the preliminary heating of a hot plate, cap or bulb, for ignition purposes.

Numerous attempts have been made by different designers to overcome the objectionable features of both the Diesel and the Semi-Diesel types and to develop a low compression engine possessing high operating economy.

The Ingersoll-Rand Company along with others entered this field, made an extensive study of heavy oil engines and, as a result of their researches and experiments, recently placed on the market a line of stationary and marine oil engines of a distinctly new type.

These new engines are different from any other oil engine on the market, being neither of the Diesel nor Semi-Diesel type, although it is asserted that they possess the advantages of each type with none of their disadvantages. They are known as the Ingersoll-Rand, Price Rathbun type, heavy oil engines, and operate with highest economy on a new principle, which permits their simplification to a remarkable degree. Engineers who are familiar with the extreme simplicity of the ordinary gas engine, can well appreciate what has been done in this line.

In the past, heavy oil engines of high economy have operated on cylinder compressions of between 500 and 600 pounds air pressures of approximately 1,000 pounds per square inch being used for the injection of fuel, thus requiring the use of a two or three stage air compressor attached to the engine itself, or separately driven. In either case the power required to operate them amounted to at least 10 per cent. of the total power output and they required considerable attention on the part of the operating force. All this troublesome and inefficient air injection equipment has been eliminated in this new engine, and it has demonstrated some things heretofore considered impossible.

In a rigid 72-hour test conducted a few months ago a three-cylinder engine built for central station service in Cuba showed at full load an average fuel consumption of 0.425 pounds of fuel per brake horse-power hour, with a compression pressure of less than 200 lbs. per square inch. At three-quarters load the average fuel consumption was 0.45 lbs. and at half load 0.51 lbs., the oil used being of 28° Baume. In considering the fuel economy of this engine (approximately 0.4 lbs. per brake horse-power hour), it is interesting to remember that in marine practice it has been customary to give fuel economies on the basis of indicated horse-power, and inasmuch as the mechanical efficiency of a Diesel engine is about 75 per cent., 0.4 of a pound per brake horse-power is equivalent to 0.30 lbs. per indicated horse-power hour for the Diesel engine.

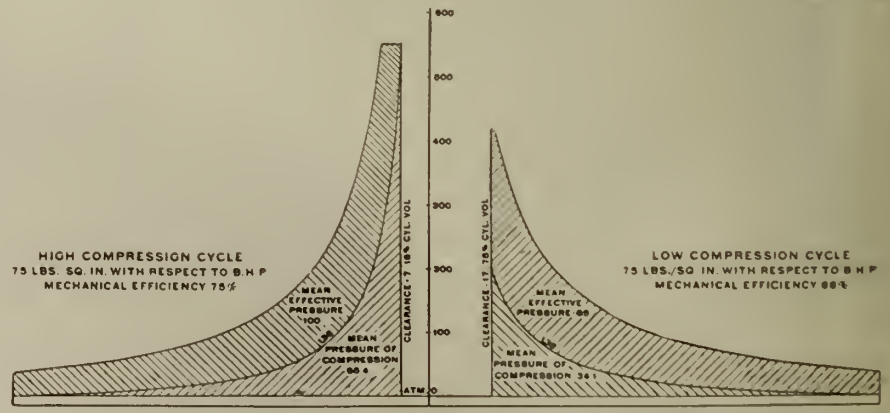


FIG. 1—DIAGRAM ILLUSTRATING MARKED DIFFERENCE BETWEEN HIGH AND LOW COMPRESSION CYCLE.

In other words, the Diesel engine would have to operate at 0.30 lbs. per indicated horse-power hour to equal the figures given for the new engine.

Cycle of Operation

The engine operates on the four-stroke cycle, with low compression (approximately 200 lbs. per square inch), with direct fuel, or as it is sometimes termed, solid fuel injection, and is absolutely independent of hot tubes, bulbs, caps and starting torches, nor is it a surface ignition engine.

The inlet valve is opened mechanically and the piston travels downwards on the suction stroke, drawing in a full charge of pure air. The intake valve is closed by its spring and the piston returns, forcing the air from the cylinder into the combustion chamber and compressing it to a pressure of approximately 200 pounds per square inch.

Injection of fuel starts near the end of the compression stroke and is completed before the piston reaches the end of its travel. Perfect working stroke combustion at constant volume occurs almost exactly at dead centre, the pressure rises from 200 to approximately 400 lbs. and the piston moves downward on the working stroke.

Near the end of the working stroke the exhaust valve is opened mechanically, the pressure drops, and the piston expels the burnt charge on its return.

Various Cycles

The cycle of this new P. R. engine is closely related to that of the ordinary four-cycle or automobile engine, and the marked difference between this cycle and that of engines of the high compression type is clearly indicated by Figure 1, while comparative indicator cards for the Diesel, the Ingersoll-Rand, and a Corliss engine are shown in Figure 2. It will be noted that the cycle of the new engine falls in between the Diesel and Corliss engine cycle. The ratio between the amount of work delivered by the engine and the amount of work done in the engine cylinder during the compression and expansion strokes is 35 per cent. for the Diesel, 49 per cent. for the Ingersoll-Rand, and 75 per cent. for the steam engine. This ratio may be called "The co-efficient of durability" or "power factor" in the same sense as the expression is used in electrical computations. An alternator which has a power factor of 75 per cent. is performing within itself 100 units of power, of which 75 units are available for use. The life of an engine, the cost of lubricating oil, repairs and attendance required is indicated by this power factor or "co-efficient of durability." In other words we have the Corliss with a high power factor of 75 per cent. lasting for very long periods and requiring very little lubricant, repairs or attention. Next comes the new engine with its power factor of 49 per cent. indicating that it will last 40 per cent. longer and require correspondingly less lubricant and attention than the other, with its 35 per cent. power factor.

Advantages of Low Compression Cycle

In the Ingersoll-Rand cycle, as already mentioned, the compression is carried to approximately 200 lbs., when combustion at constant volume occurs, raising the pressure to about 400 lbs., at which point almost perfect adiabatic expansion begins. In the high compression type the pressure is carried about 500 lbs. and oil is admitted gradually, so as to produce combustion at constant pressure until the piston has travelled a portion of its stroke, from which point expansion begins. Thus there are four points of particular advantage in the low compression cycle.

First, a lower ignition temperature is required, due to the elimination of the refrigeration action of the injection of air in the Diesel engine, as it expands from 1,000 pounds per square inch down to the cylinder compression pressure. Second, the engine we are discussing does not require an air compressor for fuel injection, friction losses are lower, and—due to its higher mechanical efficiency—the mean effective pressure which is proportional to the net work developed in the engine cylinder for the same brake horse-power of engine need only be 85 per cent. of that of the high compression cycle.

The mean pressure of compression which is proportional to the work done in the engine cylinder during the compression stroke is approximately half that of the high compression cycle, and although it is true that this work is not lost, but returned to the piston during the expansion stroke, nevertheless the performance of this extra work of compression by the piston and the return to the latter of an equal amount of excess work during the expansion strike represents considerably more wear on the piston, cylinder and bearings. For equal brake horse-power the low compression cycle subjects the engine to about 30 per cent. less wear. Parts of equal dimensions will therefore wear considerably longer and require much less attention.

As previously mentioned, the new engine is free from hot caps, tubes, bulbs, uncooled apron castings, etc., an electric igniter being used for the first few ignitions when "starting cold." The absence of hot caps or hot surfaces of any kind is of great advantage in eliminating overheating troubles at full load and underheating troubles at light loads. As there are no highly heated parts, a full charge of air can be drawn in, instead of heated, expanded, and reduced in volume. This is one of the ways in which the higher power attained with this engine for a given piston displacement may be accounted for. The splitting of hot caps is eliminated, the absence of starting torches reduces the fire hazard, and tends to make a cleaner and cooler engine room. The engine being comparatively cool at all points, the operator is enabled to attend to it with greater ease.

Fuel Supply and Injection

A pump driven from the engine elevates the oil from the main supply to a filter of special construction located at one end of the platform from which the oil is fed to the fuel injection pumps by gravity. The fuel injection pumps, one for each cylinder, are mounted on the housing near the cylinders and operated by cams from the side shaft, which also drives the centrifugal governor used to control the amount of fuel injected and vary the intake of air so as to maintain

the cylinder temperature under various loads.

Fuel is injected by the fuel pumps without the use of air injection equipment and the economy is said to be just as high, or even higher, than that of the most complicated air injection engine.

The question that will naturally be asked is this: How does the engine operate without injection air? The answer is simple: The fuel injection system used reduces the fuel to such extremely small particles that a tremendous amount of oil surface is exposed to the action of the increasing temperature obtained during the latter part of the compression stroke. The fuel injection system thus pulverizes the fuel to a "fog cloud" and at the same time obviates the impingement of the oil upon the walls of the combustion chamber.

So perfect is the "fog cloud" formed that it has been found possible to inject the oil with the engine at rest, allow the fog cloud to dissipate and then demonstrate that the walls of the chamber were perfectly dry. The fuel sprays are located at diametrically opposite points on the combustion chamber, so that they are not only balanced against each other, but the resulting motion of the "fog cloud" after impact is opposed by the air coming up through the passage from the cylinder to the combustion chamber, as will be noted by referring to Figure 3. Injection of the fuel begins about 40 degrees before compression dead centre and ends about 10 degrees before compression dead centre.

High Fuel Economy

A statement that one sometimes hears from those who do not realize that economy and dependability are intimately related is that, since the fuel cost of an oil engine is so low, a gain in economy is a small factor, dependability being the principal requisite. Every heat unit in the fuel, however, that is not transformed into useful work must be dissipated in some way. Either through the walls of the combustion chamber or through the cylinder walls to the water in the jacket, or else it is carried past the exhaust valve and its seat during exhaust, or it may disappear as friction in the bearings or cylinders with consequent bad effect on the upkeep and durability of the engine.

If the engine is inefficient, not only is a large percentage of useful fuel wasted, but in getting rid of the waste heat more or less rapid deterioration results. The waste oil must be added to the fuel bill, or paid for in additional lubricating oil required to preserve the oil film on the overheated piston and cylinder walls; or else paid for in the increased amount of cooling water required to dissipate the waste heat and ultimately in engine upkeep. High fuel economy means, therefore, low fuel cost, low lubrication cost, low cost of cooling water, lower cost of repairs and longer engine life.

It is perhaps needless to say that when an oil engine operates at such high economy as does the type described, no carbon will be deposited in the cylinder and that the exhaust will be practically colorless. The cylinders of these engines after long periods of continuous operation are said to look as clean and bright inside as do the cylinders of a high-grade steam engine, and the piston and rings also remain bright and free.

General Description

The Ingersoll-Rand "P.R." stationary oil engine is of the vertical multi-cylinder, single acting, four cycle type and is offered for general power plant service for either belt or direct connection to alternators, direct current generators, or other classes of machinery. It is said to be especially suitable for driving alternating current generators in parallel and is built at present in seven sizes, with capacities of 105 to 480 brake horse-power. It consists essentially of a heavy base or bed plate, to which is bolted a housing carrying the cylinders with their heads, manifolds and fuel injection pumps.

Base and Housing

The bed plate is of heavy construction and simple design, cast so as to form a reservoir for the lubricating system. Ribs and broad flanges give rigidity and ample bearing on the foundation. The crank shaft bearing pedestals are also cast integral with the base, as can be noted by referring to Figure 4. The housing which encloses the driving parts and forms the top half of the oil reservoir is a strong ribbed casting provided with ample means for gaining access to the interior. Doors placed at the back directly opposite the crank throws permit easy inspection or adjustment of the driving parts, while a single cover bolted to the front of the engine and supported on swinging hooks, trolleys and slide rails suspended from the platform, permits access to the side shaft, governor, eccentrics, etc. This arrangement is shown in Figure 5. Working stresses in the housing are eliminated by the use of stay bolts or tie rods, which transmit the working stresses from the top of the housing to the bed plate.

Main Bearings

Four bearings are used on the three cylinder engine and five on the four cylinder size, and as there is perhaps no other one feature in the design of the vertical multi-cylinder oil engine that has more to do with its mechanical upkeep, the main bearings of the engine have been designed along lines which ensure true and permanent alignment, and provide for quick and easy adjustment. As shown in Figure 4, the bear-

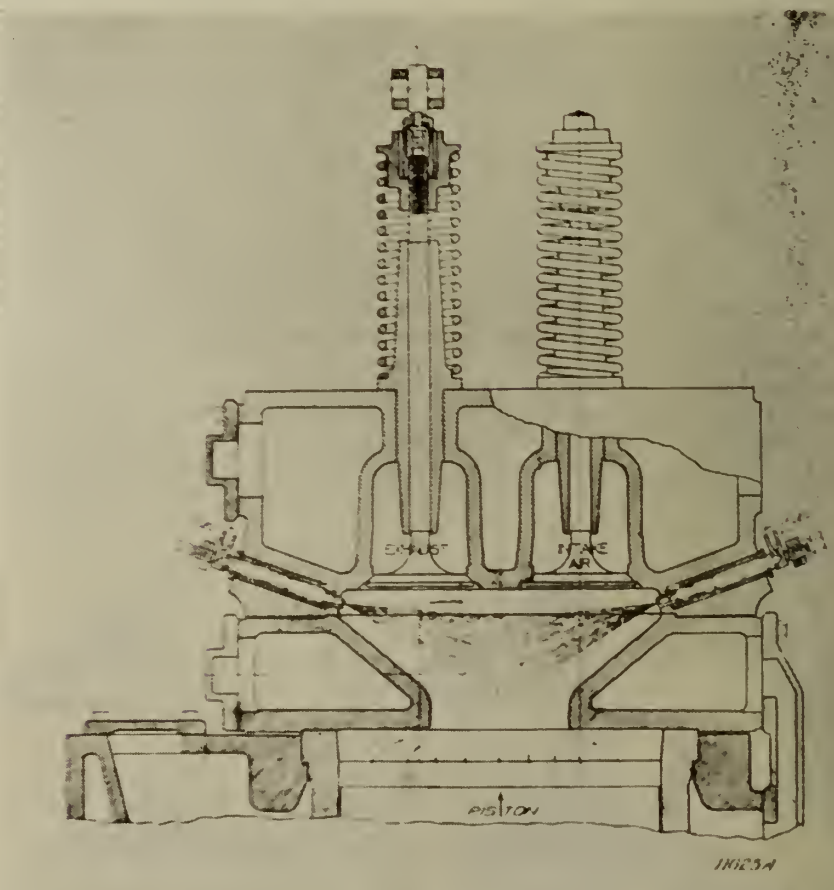

FIG. 3—CROSS SECTION OF COMBUSTION CHAMBER SHOWING LOCATION OF FUEL INJECTION NOZZLES AND MOTION OF FOG CLOUD.

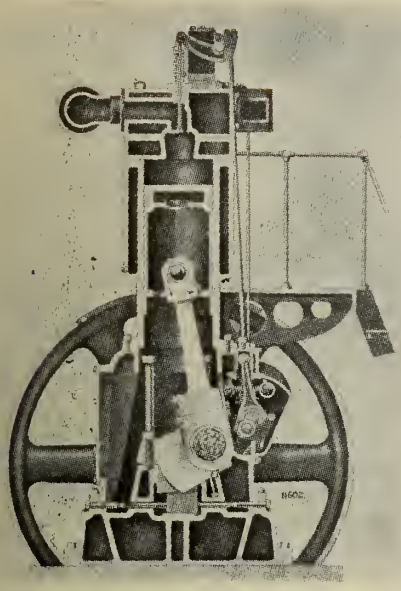

FIG. 4 CROSS SECTION OF P. R. STATIONARY OIL ENGINE.

ing caps are bolted securely to the bed plate; the bottom halves are held rigidly sidewise in the bed plate and supported on wedges which are adjustable from the outside by wedge bolts. By shifting the wedges the bottom half of each bearing may be raised until the shaft is brought into contact with the firmly held bearing caps, securing perfect alignment. The wedge bolts are then tightened and prevent further movement. By removing the wedge and bolts any one of the lower bearing caps can be taken out and renewed without disturbing the other parts of the engine.

Cylinders and Heads

The cylinders are semi-steel castings, well water jacketed and supplied with conveniently located clean-out holes. The cylinder and cylinder head water jackets are connected by outside manifolds in place of the more usual jacket to jacket connection. This permits the use of metal to metal joints and eliminates troublesome gaskets and packing at points of high pressure.

Cylinder heads are in two parts, the intermediate head forming the combustion chamber and carrying the compressed air starting valve and starting element and the main head, containing fuel injection, nozzles, air inlet and exhaust passages and valves.

Pistons

The pistons are cast from a special material designed to withstand wear and avoid warping. They are carefully finished and fitted with a "fire" ring near the top, three beveled rings held by bevelled segments and flat springs near the middle and a wiper ring in the skirt. The latter prevents an excess of crank case oil entering the cylinders, or used cylinder oil entering the crank case. Surplus lubricating oil in the cylinder is conveyed to a separator and vented to the atmosphere.

Valves and Valve Motion

Valves are of the poppet type located in the head, as previously mentioned and are operated through a valve motion known as the "roller path type" from eccentrics mounted on the side shaft. Timing of the valves and fuel injection is obtained from this side shaft through the medium of a pair of spur gears driven by the crank shaft and the entire valve motion and timing mechanism works smoothly and quietly.

Crank Shaft and Connecting Rods

A solid one-piece steel forging is used for the crankshaft, ensuring uniform strength and stiffness. The connecting rods are forged from mild steel with a solid eye and adjustable bronze box at the wrist pin and a babbitted steel half box and a babbitted steel strap bolted and keyed to the rod at the crank pin end.

The Fly Wheel

The flywheel is of the split hub type, massively constructed and acts as a strong and rigid coupling between the main shaft and the extension shaft, the dimensions of which vary according to the requirements of each installation. A self-aligning outboard bearing provides additional support for the extension shaft.

Lubrication

As previously mentioned, the bed plate and housing are arranged to form a reservoir for the automatic lubrication system. Adjustable dippers on the connecting rods dip into the oil at each revolution and drench the working parts with oil. Troughs on the inside of the housing catch part of the oil and convey it through pipes to the main bearings. In operation, oil from an elevated filter is supplied to the main bearings through open sight feed oilers, insuring a constant supply while the engine is running. The oil level in the base is adjustable and the overflow is returned to the filter by a small pump.

Starting

Electric ignition—by means of a small element in the combustion chamber, heated to a dull red—is employed for the first few revolutions, when the engine is absolutely cold, while compressed air from a tank under pressure of 150 pounds is admitted to each cylinder in succession by means of mechanically operated starting valves and serves to turn the engine over. As the engine is turned over fuel is injected and after a few revolutions the air and ignition are cut off and the engine continues to ignite entirely by compression. Where compressed air and electricity are not available for starting purposes they are usually provided by a small gasoline or kerosene oil-driven compresser and a belted generator.

T. W. Lesage, for eleven years superintendent of the Montreal Waterworks Department, will resign from the city service at the close of the year. Mr. Lesage entered the service of the city thirty-three years ago, and his start was in charge of construction work. In 1890 he was appointed assistant engineer to the city surveyor. In 1900 he was transferred to the waterworks department, taking the position of assistant superintendent. In 1911 he succeeded Major Georges Janin as superintendent. A year ago he was superseded by Supt. Terrault, and for the past twelve months Mr. Lesage has acted in the capacity of consulting engineer for the city.

NEW FUEL

A new compound fuel, named thermalene, has been produced by Karl Wolf, of Zurich. It is a mixture of acetylene and vaporized oils, and is claimed to have important advantages over other gases as a fuel for high temperatures. As now manufactured, the generating mixture, consisting of alternate layers of calcium carbide and crude oil absorbed in sawdust, is packed in tin cans, the largest yielding 200 cubic feet of gas. The addition of water liberates the acetylene, and the heat of the reaction converts the oil into vapor. The two gases are cooled and purified, ready for use in the pipes. The gas mixture is not corrosive or poisonous, has an inoffensive odor and is not liable to cause explosions. At normal temperature, thermalene, which is somewhat heavier than air, is liquefied by a pressure of 1,500 pounds or 1,600 pounds per square inch.

BENDING PIPE

Bending pipe is by no means a simple task. There is always a right and a wrong method. In bending large pipe you should fill the pipe with dry sand and plug the ends. Heat to a red heat in localities to be bent, then bend. Be sure that the sand is dry. Where bends are slight it is often unnecessary to use sand or rosin. The object of sand or rosin is simply to keep the sides of the pipe from collapsing, or, to prevent reduction of flow area. If wet sand is used, and if the ends are plugged, the pipe may burst when heated, due to the steam pressure generated.

Rosin is also good. But there is a "right way" and possibly several wrong ways to use it. For example: A mechanic was recently bending a pipe, and he first of all filled the pipe with rosin, plugged the ends, and heated the pipe at the place where he wanted to bend it. He watched for a "red heat" just as he would had he filled the pipe with sand. The result was of course a violent explosion.

The correct way to use rosin is to pour it into the pipe and allow it to cool and harden. As soon as the rosin is hard, bend the pipe cold. Don't heat it. Then after the pipe is bent, heat the pipe all over sufficiently to melt and remove the rosin.

A Course of Instruction For the Graded Certificate

This Instalment Deals With the Effect of the Angularity of the Connecting Rod on Steam Distribution, and Introduces the Subject of Valve Diagrams

By T. H. FENNER

IN the last lecture it was shown how the positions of the valve, eccentric, crank and piston were related during the stroke of the piston. There is one point to observe in this connection. With the ordinary length of connecting rod it is not possible to get equal distribution of steam at each end of the cylinder unless special provision is made for it.

Angularity of Connecting Rod

The effect of the obliquity of the connecting rod, or to make it clear, the angle the rod makes with the centre line of engine, is to change the relative position of valve and piston at certain points of the stroke. If the connecting rod were always of sufficient length to be practically parallel to the centre line of engine this would not take place. If the eccentric rod was of the same length in proportion to the eccentric as the connecting rod is to the crank the effect would be neutralized. However, neither of these conditions occurs in actual practice.

The connecting rod is generally from 2 to 2½ times the length of the stroke, or 4 to 5 times the length of the crank. The eccentric rod is so long in respect to the eccentric that the rod is practically always parallel to the centre line of the engine.

The angularity of the connecting rod causes the piston and crank to differ in their relative positions at certain parts of the stroke, but the eccentric always remains in the same position relative to the crank. As the eccentric rod is long enough to keep the valve always coincident in position to the stroke of the eccentric, it can readily be seen that the valve will be out of relation to the piston when the piston is out of step with the crank. The particular result is to cause steam to be cut off earlier on the inward stroke of the piston than on the outer. To overcome this, it is usual to give the valve more lead on the crank end than on the head end, when the valve is made with equal steam laps at each end. The same result can be achieved by giving the valve the same lead but less amount of steam lap at the crank end. This will be shown more plainly when we consider the valve diagrams.

This subject of the connecting rod and its effects has often been very troublesome to the student. We will try to make it perfectly clear by means of the following diagrams.

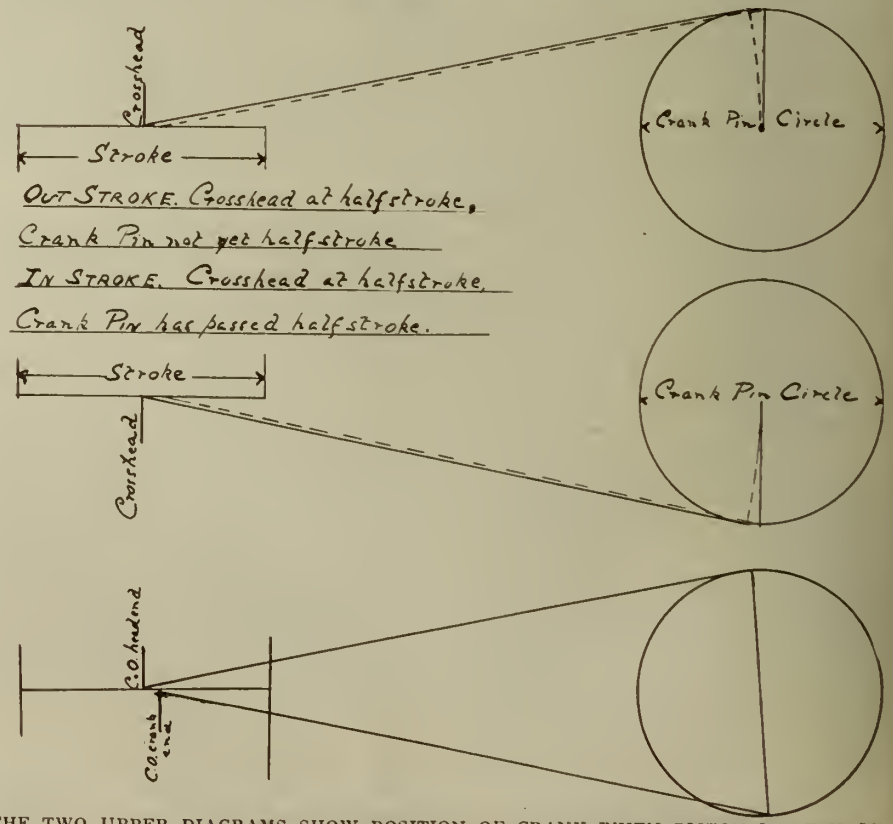
The stroke is 2 inches and the connecting rod 5 inches. On the outstroke the crosshead and therefore the piston has reached half stroke before the crank has turned through 90 degrees. When the crank is at 90 degrees the piston is more than half stroke. On the inward stroke, when the crank has turned through 90 degrees, the piston is not yet at half stroke, and only after the crank has turned a little distance past the 90 degrees does the piston reach its mid position. A little thought will show what effect this will have on the steam distribution. Let us suppose that we have arranged for this engine to cut off at half stroke. On the out stroke the crank will be just short of the half stroke when steam is cut off but the piston will be at exactly half stroke. Now if we have equal lap and lead on the valve, cut off at the crank end will take place when the crank has moved through 180 degrees from the head end cut off position. It will be readily seen from the lower diagram that the piston will not have reached half stroke. It is in order to counteract this effect that the valve is set with more lead on the crank end than the head end, thus making the cut off later, and giving more nearly equal steam distribution.

Valve Diagrams

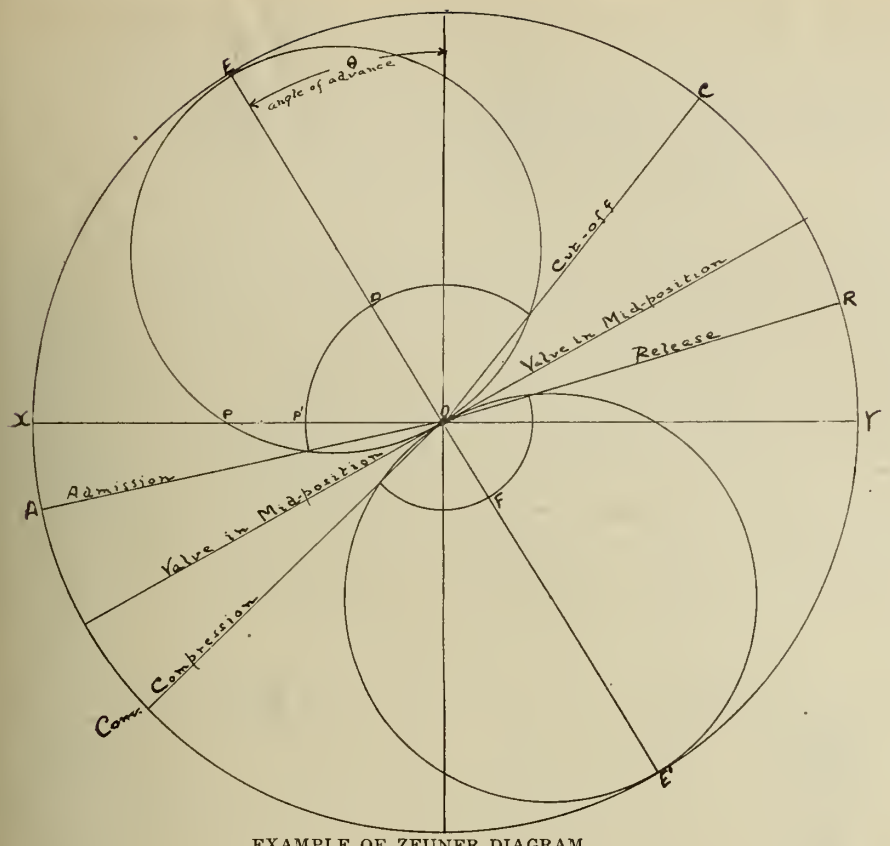
In order to give more information and in an easy way, several diagrams have been evolved which give the position of the valve at a glance, or from which the various points can be determined. The most popular of these is the Zeuner, and it is a very useful and convenient thing to study valve motion from.

To construct a Zeuner diagram, describe a circle to represent the path of the eccentric and also the path of the crank pin on a smaller scale. That is, the same circle represents the two travels, eccentric and crank. Assume a certain angle of advance, and lay this off from the centre line towards the crank. Be clear on this. The angular advance is laid off towards the crank in the diagram, although it is of course away from the crank in the engine. Draw a line from the centre of the circle to join the circumference at the angle of advance and produce it through the centre O to the opposite diameter. Call the two points where the circumference is cut E and E'. With OE and OE' as diameters, describe two circles. These circles are called the valve circles, and the circumference of these circles gives a line for locating the various valve positions.

As it is the outside lap that governs the steam admission and cut off, an arc



THE TWO UPPER DIAGRAMS SHOW POSITION OF CRANK WHEN PISTON IS AT HALF STROKE. THE LOWER DIAGRAM SHOWS POSITION OF PISTON AT CUT OFF WHEN LEAD IS EQUAL BOTH ENDS.



EXAMPLE OF ZEUNER DIAGRAM.

of a circle with radius equal to the outside lap is drawn with O as a centre, and by drawing lines through the points where this arc cuts the valve circle we obtain the crank position for admission and cut off, A and C. The length of the line from the centre to the valve circle gives the travel of the valve from its mid position at that point. A line drawn across the diameter of the eccentric circle, tangent to the two valve circles, gives the position of crank when valve is in midposition.

So far we have got the operations for the steam edge of the valve. We now require those for the exhaust. To obtain these positions we draw an arc equal in radius to the inside lap of the valve, and cutting the lower valve circle at the circumference. If we now draw lines from the centre of the eccentric circle through the points where the arc cuts the valve circle, the one to the right represents the crank position at release, and the one to the left the crank position at compression. The length of the lines from centre of eccentric circle to circumference of valve circle gives the displacement of valve from its midposition. Likewise the length of line between lap circle and valve circle represents the port opening. Thus it will be noticed that with crank at dead centre the port opening is represented by the length of line P P. At the cut off point, release and compression, the three lines coincide, and also at the admission point. The lines D E and E F represent the maximum port opening.

It will thus be seen that here is a quick and easy method of finding out all about the motion of a slide valve. By it valves can be designed, or the action of the present valves checked up. The effect of moving the eccentric either ahead or back can be plainly seen on the diagram. Increased inside or outside lap reflects its influence on the diagram in a way that is unmistakable.

We will deal with the diagram further in our next article.

TO MAKE FUEL CONTRACT

W. L. Chandler, of the Dodge Sales & Engineering Co., Mishawaka, Indiana, president of the National Association of Purchasing Agents, has called a meeting of the Fuel Committee of this organization to be held at the William Penn Hotel at Pittsburgh on February 18 and 19.

The purpose of this meeting is for the fuel committee to meet and discuss a fair, equitable, and inviolate form of contract governing the purchase and delivery of coal.

There will be about thirty-seven members of the fuel committee present, each representing a local association. Ernest H. Hawkins, E. I. duPont de Nemours Company, Wilmington, Delaware, will act as chairman of the committee and of an advisory council of five members of the fuel committee.

It is the purpose of the fuel committee to reach some form of contract which may be standardized and at a later meeting the advisory council will meet with representative coal operators, distributors and purchasers to secure their advice and co-operation relative to the provisions of the contract as worked out at this meeting.

The proposed contract form is attracting wide attention according to the New York headquarters of the National Association who report receipt of several hundred letters from some of the largest and most influential organizations in the United States, discussing the proposed contract from various angles.

C. A. S. E. TORONTO OPEN MEETING

On Wednesday, February 23, the Canadian Association of Stationary Engineers, Toronto Lodge, will hold an open meeting in the Temple Building, Bay Street, at 8 p.m.

This promises to be an interesting evening, the subject of the lecture to be given being "Diesel Engines." The Diesel will be described and illustrated by slides, and the lecturer will be Mr. Brown, who designed the first true Diesel to be built in Canada.

In view of the important place this type of engine will probably assume in the near future, all those who can do so should take advantage of this opportunity. They will be sure to enjoy it.

CHIMNEY TEMPERATURES

An instrument has been produced for ascertaining the temperature of a chimney at various depths. The apparatus consists of three tubes extending to various depths, and enclosed in a long, pointed steel case. These tubes end in bulbs, and are filled with alcohol. At the upper end of the instrument are three dial temperature indicators, each connected to a tube. The scales on the dials range from 32 deg. to about 200 deg. Fah., and are colored black up to 120 deg., but upwards from that temperature the color is red, indicating excessive heats. If several of these devices are forced into a coal pile at varying depths and in different localities, accurate information can be gathered for the whole of the pile. It is stated that instruments employed at intervals of 50 ft. have proved very effective.

Fatal Accident.—Lying on his stomach, looking down an elevator shaft in the Sunbeam Lamp Works, 221 Dufferin street, Toronto, George J. Pond, aged 45, of 15 St. Clarens avenue, was crushed to death by the elevator cage. Fred Read, 146 Booth Avenue, was searching at the foot of the shaft with a lantern for a gold locket which had been dropped. He was standing in the pit below the basement and the elevator does not descent below the level of the basement. This saved Read from meeting with the same fate as Pond. The machinery of the elevator was started through some unknown agency, and the cage slid down the shaft pinning Pond and crushing his skull. The body was removed to the Morgue, and an inquest will be held. Mr. Pond is survived by a widow and six children.

Some Points on Erecting and Lining Up

Erecting Shop Practice is Introduced, and the Complete Process Of Erecting Will be Explained. The Present Article Deals With the Main Frame Castings of a Horizontal Engine

By "Fitter"

THERE seems to be a considerable amount of difficulty on the part of some young engineers in mastering the art of lining up.

It is not a very difficult matter, but one that calls for care and accuracy in making a few simple adjustments. Lining up is usually called for in an engine that has been in service for some time, but it is also required when the engine is first erected in the erecting shop of the firm that makes it. The engine has again to be lined up when it is set up in the engine room of the purchaser. On neither of these occasions does the operating engineer have much to do with it. In the first case he has nothing, and sometimes in the second case the engine is erected and has had a trial run before he comes on the job. Thus it may happen that an operating engineer is a good many years at the trade without running into the problem. For the benefit of those who have had no shop training it might be of help to give a brief outline of the method pursued in erecting an engine in the shop.

Erecting Shop Practice

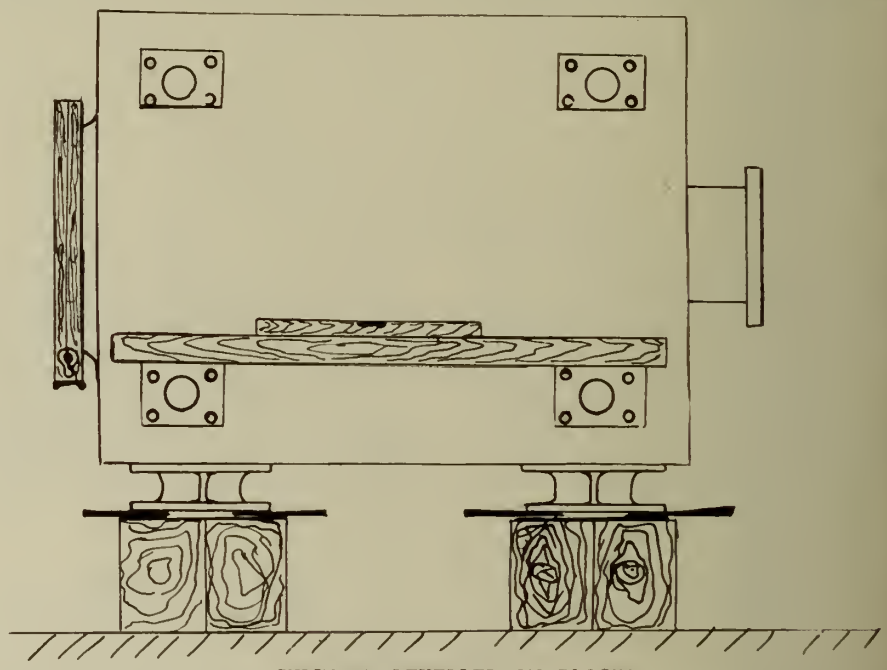
The first part to be erected in a horizontal engine is the cylinder. In a vertical engine, of course, the cylinders cannot be put on until the bed plate and columns are set up. We will consider the horizontal engine first, as this is by far the most common type. Let us take the example of a Corliss single cylinder engine, with overhung crank, fly wheel, and outboard bearing.

The cylinder comes to the erecting shop after being bored to the correct size, stuffing box bored out, and faced, cylinder faced for the cover, holes drilled, and tapped for the studs, valve chambers bored out, the ends of the valve chambers faced off to receive the covers, with holes drilled and tapped, and holes for indicator connections and drain cocks drilled and tapped. The studs may also be put in by the fitting shop gang or they may be put in by the same machine that does the drilling and tapping. Practice varies in this particular.

Square blocks of timber are laid on the floor at right angles to the line of the engine. These are for the cylinder feet to stand on, and it is good practice to lay a sheet of 18 to 20 gauge iron on the top of the timber. Iron wedges are kept in readiness, and as the cylinder is swung up by the shop crane, and brought over the timbers, the wedges are placed on the sheet iron, so as to support the cylinder when it is lowered. There are usually four feet or supports, one at each corner of the cylinder, and it is a good thing to put four wedges under each foot. This allows of easy adjustment. The placing of the sheet iron on top of the timbers allows easy movement of the wedges as they are tapped in or out. If placed directly on top of the timbers they would cut into the wood, and render readjustment difficult.

Having landed the cylinder, the next thing to do is to level it up. It must be levelled both in a longitudinal and transverse direction. Vertical and horizontal centre lines will probably have been marked on the cylinder end by the marker-off, when he laid out the stud holes, and also the mark for boring. If they are not available, they can be made from the drawing, which shows the position of the studs. It is usual for a stud to be placed on the vertical centre line top and bottom, and very often there are studs on the horizontal centre line. If this is the case, a steel straightedge can be laid across these studs, and a spirit level placed on the straightedge. This will give the horizontal setting. If this cannot be done, a plumb bob can be dropped down the centre line and the cylinder adjusted till the vertical centre line coincides with the string of the bob. If there are studs on the vertical centre line top and bottom the steel straightedge can be placed against these studs and a plumb rule or spirit level plumb rule placed against the straightedge. Either of these ways will give the desired result.

To get the cylinder level in the longitudinal direction, the spirit level can be placed in the cylinder bore, but this is not a very handy way to read it. In levelling, it is best to get the reading over as long a distance as possible. A short level laid on a true surface may show true, but if the same level is placed on a straightedge laid across two planed surfaces some distance apart, and moved along from one end to the other, a slight amount of out-of-lineness is plainly shown. Therefore it is better to lay the straightedge across the top of the valve chamber faces, which are usually machined. If this cannot be done, the cylinder can be levelled by the plumb rule placed across the end of the cylinder, which will give it in a satisfactory way. In any case, this can be used as a check, even if the spirit level can be used horizontally.



CYLINDER LEVELLED ON BLOCKS.

The cylinder is now level in every direction, and ready for the placing of the girder frame. This girder frame is in some cases cast integral with the main bearing casting and in others is a separate casting, bolted to the cylinder at one end and the main bearing casting at the other. In either case, it must be absolutely in line, as it carries the crosshead guide shoes and forms the guides for the piston rod. These girder frames are usually bored out to carry the circular guide shoes and the holes will have been drilled in the frame to receive the studs on cylinder and also on main bearing casting. The pitch circle of these studs will be concentric with the circle to

which the guides are bored, so that when the frame is bolted up, it will have its centre on the centre line of the engine. If the frame is cast together with the bearing casting, then this will have to be blocked up level at the same time. In this case the crane would pick up the whole frame and pillar block casting, and the blocking would be put in under it and the cylinder end eased on the studs at the same time. Care would have to be taken to see that the bearing was blocked up high enough to take any bending strain off the studs before the crane is slacked off. If the girder is separate from the main bearing casting it can be fastened on to the cylinder studs and the far end blocked up in readiness for the main bearing casting. The main bearing casting in this case would be landed on blocking with the studs just clear of the frame girder, and with the blocking so arranged that the casting could be pried over till the studs had entered the holes all fair. It would then be pushed to its place.

The main part of the engine is now in place, consisting of cylinder girder frame and main bearing. The next thing to do would be to go over the whole frame again with level and plumb to make sure that it is level from end to end and also sidewise. The top of the main bearing casting being planed makes a good surface to level off, and the circular guides on the girder frame make another levelling point. A long straightedge laid on the guides should be used, as otherwise the level may be thrown off by the radius of the guides. Straightedges that give a longer surface to run the level over than the surface being levelled should always be used.

Having ascertained that the frame is dead level all ways, the outboard bearing can be put down in a position approximating its final position. It will, of course, be laid on blocking in the same manner as the other parts, so that it can be easily adjusted.

The next job will be to line up the bearings at right angles to the cylinder centre, and check up the dimensions of journal boxes and bottom brasses to see that the centre line of crank shaft comes in line with centre line of engine.

(To be continued)

The Use of Chains and Other Lifting Gears

THE department of internal affairs in London, England, have issued a pamphlet dealing with the use of chains and other lifting gears. This subject is dealt with in considerable detail, but the data to follow form the portion that we believe will be of especial interest to our readers.

The safe working load for chains is given, in tons, as six times the square of its diameter. This differs from the American rule, which is $2.8d^2$—this giving a factor of safety of 4.5. Descriptions of the various types of chain and attachments are given, and the table, as shown in this article, is used to illustrate the safe loads that can be put upon two-legged slings, with the legs at various angles.

The pamphlet also includes some remarks on the testing, inspection and annealing of chains, and concludes with the following summary of precautions:—

(1) Chains and other appliances used for lifting purposes should be obtained from reliable manufacturers. The maximum working load and the purpose for which the chain or appliance is to be used should be clearly stated when ordering.

(2) No chain or other appliance should be used for lifting or similar purposes unless—(a) A test certificate has been obtained from the manufacturers showing the proof load to which it has been subjected and the name of the person responsible for the test; (b) a guarantee has been obtained from the manufacturer as to the quality of the material used, and that the chain or appliance has been thoroughly examined by a competent person after testing and found free from flaws, defects or deformation.

(3) The necessary information should always be available for any person using a chain or other appliance, to enable him to ascertain the safe working load for such chain or appliance.

(4) The maximum working load for any short or close-link chain should not exceed $6d^2$ tons, when used under normal conditions without shock; $5d^2$ tons, where there is any special danger to life or limb, or $3.5d^2$ tons where the chain is subjected to shock or heavy wear, or is used for lifts of molten metal or heated liquid; d being the diameter in inches of the iron of the chain. The maximum working load for a long-link chain should not exceed two-thirds of that for a short-link chain of the same diameter.

(5) When chain slings with two or more legs are used with the legs inclined, care should be taken to ensure that the maximum load in each leg does not exceed that given in recommendation 4 of the table shown.

(6) When the actual weight of an article to be lifted is not known, an approximate computation should be made, and lifting appliances should be used which allow an ample margin of safety.

(7) Load indicators and overload detectors should be used in connection with lifting appliances, especially jib or derrick cranes, whenever reasonably practicable.

(8) Slings or other chains should never be shortened by tying knots in them, and wood or other suitable packing should be provided to prevent the links coming in contact with corners of loads of hard material.

(9) Sling chains and other lifting appliances, when not in use, should be stored under cover and kept on suitable racks or pegs.

(10) Every chain or appliance used for lifting purposes should be marked with an identifying letter or number, either on the chain or appliance or on a tablet attached thereto.

(11) All chains and other lifting appliances should—(a) If used for lifting in connection with molten metal or molten slag, be examined at least once in every month and be annealed at least once in every six months; or (b) if used in connection with lifting machinery or plant operated mechanically or electrically, or used for lifting in metal foundries other than that mentioned in paragraph (a) above, be examined at least once in every three months and be annealed at least once in every twelve months; or (c) if used for classes of lifts other than those mentioned in (a) and (b) above, e.g., in connection with hand cranes, be examined at least once in every six months and be annealed at least once in every two years; or (d) if used for holding down any crane or other lifting machinery upon a stage or platform should be examined as far as reasonably practicable, in situ, at least once in every three months, and be fully examined and annealed at least once in every twelve months, unless the nature of the operations preclude such examinations and annealing.

(12) A chain or other appliance should not be used for lifting its maximum working load if the wear at any part exceeds 10 per cent. of the nominal dimension of that part, or for lifting any load if it has been subjected to a severe shock or is deformed or otherwise injured.

(13) A chain or other appliance which has been altered or repaired should be re-tested before use.

(14) A record with full particulars should be kept of every chain or other lifting appliance.

Don't Lose Your Interest

TWO recent letters in the daily press, both apparently written by members of the stationary engineering fraternity, are worthy of notice. The first of these letters called attention to the waste of fuel that goes on day by day in industrial and domestic furnaces. The second one fully endorsed all that the writer of the first had to say about waste and the remedies for the same, but claimed to be in a place where it was impossible to interest the boss in such a matter as fuel conservation.

The writer of this letter claimed that the plant he was in was run in a wasteful manner as far as fuel was concerned and no amount of representation on his part could remedy matters. The result was that he was about to give up in disgust. Though it seems hard to believe that in these days there can be factory owners so blind to their own interest still we must believe that the writer of the letter was sincere in his statements. The thing is, should any man, while still remaining in charge of a plant, relinquish his efforts and let things slide? It may be perfectly true that he can go on drawing his wages just the same and with far less worry to himself if he does this and probably feel also that he is being just as much appreciated. There is one man, however, who knows he is not doing his best, and that is himself. No man who has his heart in his business and is honest to himself will go on drawing money when he is not doing the work to earn that money. He may try to comfort himself by saying that he is doing all that he gets paid for. That is a wrong idea. When a man sells his labor he should get the full market value for it, but he should on his part give the full value of what is in him in return.

There is no doubt that a large percentage of employers do their best, whether intentionally or not, to discourage the man in charge of their plant. They look on the power plant as a source of expense and not a producing part of the establishment. Every cent spent there is spent grudgingly and they rarely, if ever, give themselves the chance to learn a little about how things are run or what the engineer has to contend with. This type of employer is fortunately decreasing and we believe it rests with the engineers themselves to educate those that remain out of their wrong point of view.

The engineer who is sure of his facts and can sit down and give them in cold figures, can approach an owner or manager knowing that he can get a hearing. If you can't leave the engine room long enough to have a good talk in the manager's office, ask him to come down to the engine room and spend a little time with you. You will probably be able to set him thinking even if he doesn't respond too well the first time. Try to have a general knowledge of the requirements of the different parts of the factory from a power and heat requirement angle. Have at least an approximate idea of what your power costs are and where you can bring them down by the particular piece of apparatus you want. Know your ground and then tackle the powers that be like a man. If you can't get what you want, then do the best you can with what you have until you can find something more congenial. While you are on the job, give it your best, for your own satisfaction, the respect of your fellow engineers and the credit of the stationary engineer in general.

Central Heating Plants

THERE has been recently some renewed agitation for the central heating plant in the interests of fuel conservation. We have no doubt that the establishment of these plants where the conditions are favorable would save an enormous amount of waste. There are quite a few plants of this nature already in operation and achieving good results, but in order to do so they must be properly laid out and provision made for returning the condensed steam to the boiler. In towns of medium size where there is an electric light plant or street railway plant which operates at very low load factors for part of the time, or as in many cases, has long spells under banked fires and standby conditions, there is a very good chance of making a profitable investment of a central heating system.

In a plant of the latter class, which may be called upon to supply power at any moment, the labor costs and overhead are going on all the time, whether the plant is supplying power or not. The boilers are under steam and the standby losses which are so important a part of the costs of central stations are present for a goodly portion of the day with nothing to cover them in the way of revenue. The amount of fuel necessary beyond that used for keeping steam handy that would be necessary to supply a well-designed heating system would not be very great and would enable householders and office buildings to obtain their heating at a much smaller cost than that of running their own furnace. There would also be a considerable saving to the ratepayers in that the cost of collecting ashes by cart from each house or office building would be eliminated. Instead of unconsumed gases leaving a thousand different chimneys there would be but one chimney and that, due to efficient operation, would deliver but little smoke.

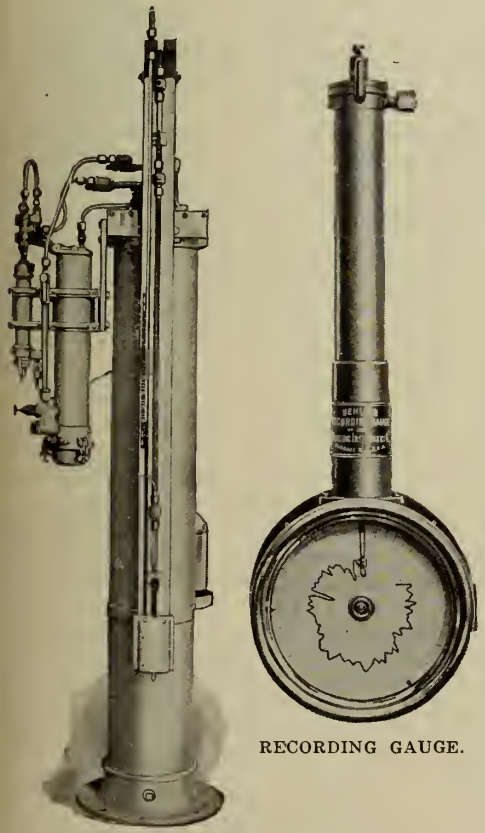
The central heating plant would be more economical, cleaner and a great deal more satisfactory to all concerned than the present method of individual heating and in a country like this it should have a very wide field.

Progress in New Equipment

NEW CARBON DIOXIDE RECORDING EQUIPMENT

Coincident with the present acute interest in better boiler economy, the Uehling Instrument Co., 71 Broadway, New York, has introduced a new model CO_2 recording equipment, known as style U, which embodies important improvements over the superseded model. Chief among its advantages are remarkably quick action, greater accessibility and simplicity of parts, and the economy of combining in one machine means for determining CO_2 simultaneously from any number of boilers, up to a total of six.

A single unit Uehling CO_2 equipment for one boiler consists of three principal parts, namely, the CO_2 meter proper, Fig. 1, recorder, Fig. 2, and auxiliary boiler front indicator, Fig. 3. The meter is placed wherever most convenient. Its function is to actuate the boiler front indicator and recorder in the engineer's office.



SINGLE UNIT METER.

RECORDING GAUGE.

The flue gas is analyzed, that is the CO_2 is extracted, in the meter. The principle involved in the operation of this machine depends upon the change in pressure caused by a change in volume in a stream of gas flowing through two apertures. Referring to Fig. 4, gas is caused to flow continuously through first aperture (A) and then (B) by means of

DRY ABSORBENT CARTONS.

an aspirator or syphon. A reduction of the gas volume between the two apertures, by absorption of the CO_2 content, causes a change of pressure or tension in chamber C which is transmitted to recorder and indicator, calibrated in per cent. CO_2.

The CO_2 meter consists essentially of a cylindrical regulator on which is mounted the analyzing mechanism. This regulator maintains constant the suction created by the aspirator, thereby eliminating all changes in tension between apertures (A) and (B) except those caused by absorption within chamber C. It is the latter changes in tension which the indicator and recorder register.

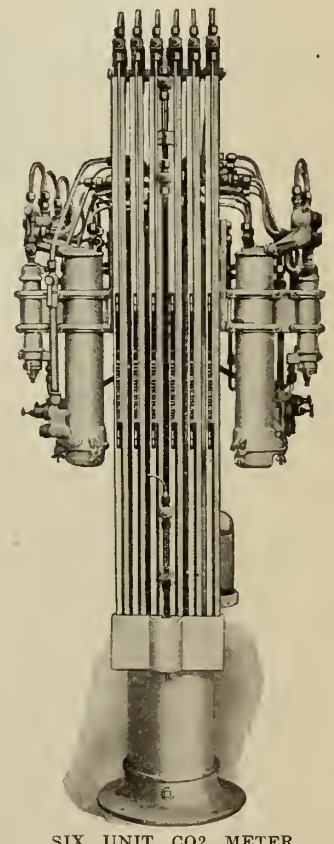
Suction in chamber C actuates the recorder and indicator instantaneously and continuously. The only appreciable lag was formerly in the travel of the gas from boiler to chamber C. In the new model the gas travel is hastened by utilizing the main aspirators exhaust in an auxiliary aspirator for the purpose of drawing the gas from the boiler up to the absorption chamber while the main aspirator draws the gas sample through the absorption chamber.

With each unit is included a preliminary filter which removes soot and dirt from the sample before it reaches the intermediate and final filters on the machine. This has been redesigned so that the filter chamber can be conveniently cleaned in a few seconds without interrupting operation of the machine.

Multiple equipments combine in a single outfit means for measuring CO_2 from 2, 3, 4, 5 or 6 boilers independently and simultaneously. It is most economical to equip the boilers in batteries of six each, but this is not absolutely necessary, inasmuch as the CO_2 meters are now built on the "unit" or "sectional" plan and may be added to from time to time. For example, a plant can purchase a single-unit, two, three, four, or five-unit equipment initially and easily attach additional units, up to a total of six, as new boilers are installed.

With multiple unit machines each boiler is equipped, as previously mentioned, with its own recorder, auxiliary boiler front indicator, preliminary filter, and absorbent chamber with necessary appurtenances, but the aspirator and other parts of the master unit serve all units in common. A six-unit meter is illustrated in Fig. 5.

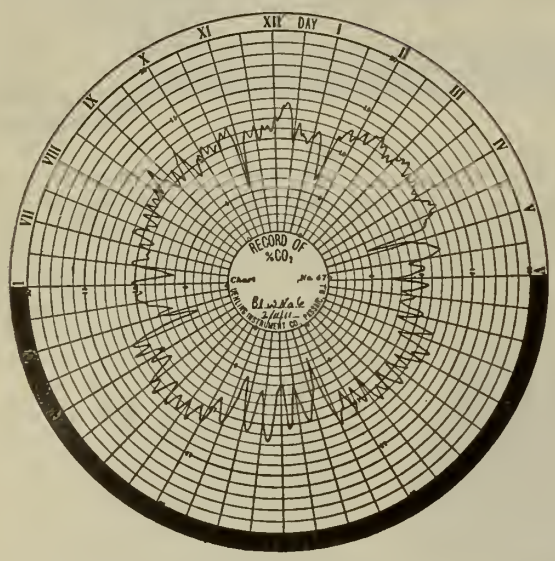
The recorder, Fig. 2, operates on the hydrostatic principle, by which all springs, levers and joint movements are avoided. It makes a continuous (not intermittent) record of the per cent. CO_2 furnishing an autographic history of the operation of each boiler for every second of the day, showing when fires receive attention; when and how often furnace doors are opened, or how often stoker



SIX UNIT CO2 METER.

speed and fuel bed thickness are changed; fires broken and cleaned; effects of changes in damper regulation and methods of firing. Thus the real facts are recorded and the fireman gets a square deal.

The boiler front indicator guides the fireman in supplying just the right amount of air to burn the fuel with the least loss of heat up the chimney.



CONTINUOUS RECORD CHART.

CO2 INDICATOR.

CATALOGUES

The Gardner Governor Co., Quincy, Ill., have forwarded bulletins describing their steam engine governors, duplex steam pumps, and duplex power pumps. The bulletins are well illustrated and give full particulars of the subjects dealt with. The pumps are designed for all purposes, and the power pumps arranged for direct motor or belt drive. The governors are of the fly ball type, with emergency safety attachments.

Escher Wyss & Co., the well-known Swiss engineering firm, announce that Mr. Th. Seidl has returned to take charge of their Montreal agency. Mr. Seidl will combine the duties of chief engineer and manager, while Mr. C. H. Withers, who has been in charge during Mr. Seidl's absence, will remain as assistant manager. The company have added to their general engineering lines some special apparatus for use in chemical works and sulphite mills.

Bulletins No. 240 and 241 of the Dayton Dowd, Quincy, Ill., describe their single and multiple stage centrifugal pumps. The multiple stage pumps are made up to four stages, but where there is necessity for more stages than this the makers advise the installation of two units. They explain that there is no limit to the number of stages that can be used in a pump, but owing to mechanical features such as distance between bearings the two unit system is recommended for all stages above four.

The Griscom-Russell Company, 90 West street, New York City, manufacture a device for the cooling of oil used in the lubrication of turbine bearings, reduction gears or quenching oil in the heat treating of steel. In either case the oil is constantly circulated through the cooler, thus maintaining the oil at a constant temperature and permitting the continued use of the original quantity of oil and its maintenance at the proper viscosity for efficient results.

The apparatus takes its name from the whirling path of the oil, which path is accomplished by the use of the helical baffle which directs the oil in its flow without appreciably retarding its progress. This baffle also serves to bring the oil into intimate contact with the cooling surface and it insures a high rate of heat transfer.

We have received bulletins from the American District Steam Co., North Tonawanda, N.Y., describing several of their products for steam plant use. These include Adsco Angle fittings, which are special flanges with slotted holes for giving an offset to pipes without the interposition of special ells. The pipe can be offset to any required degree by these fittings. The Adsco adjustable wedge is for making up two pipes which do not fall into line, and can be used for any offset up to 10 degrees. A second bulletin No. 151 describes the rotometer, a rotary condensation meter, of convenient design and size. Bulletin No. 152 describes the Adsco water heaters for domestic hot water purposes, also for institutions, etc.

The shell is of cast iron and the tubes of seamless drawn brass or copper, expanded into a fixed tube plate at one end and into a floating head at the other, which latter permits expansion and contraction without strain on the tube joints.

TRADE GOSSIP

Must Quit Union.—Twenty-two electricians, mostly outside linemen, employed by the Winnipeg City Light and Power Department, were suspended and paid off for failure to comply with the order of J. G. Glassco, manager, that they sever their connection with the Electricians' union. The men, it is understood, will be given a day or so to comply with this order, failing which they will be permanently dismissed.

The Dominion Engineering and Construction Company has been organized for the manufacture of "Delco" machinery and "Viking" pumps. A plant has been established in Longueuil across the river from Montreal, and machinery is now being installed. It is expected that the factory will be in operation within a short time. A. G. Kidston & Co., 17 St. John St., have been appointed the Canadian selling agents.

The Grand Trunk Point St. Charles shops in Montreal will be closed during the present week, for the purpose of overhauling the power equipment, general transmission and air compressors. A complete inventory has been taken recently of every machine and piece of equipment, and also the buildings, for the information of the arbitration board now sitting in Montreal, in connection with the handing over of the road to the Dominion Government.

The Engineering & Sales Service Co. of Montreal are now well established in their new premises at 179 Duke St. In addition to their sales service the company are acquiring machinery and equipment for the carrying on of a general jobbing and repairing business. It is expected that the company will be manufacturing Promet here in Montreal in the course of a few weeks. For the past couple of years the Engineering Sales & Service Co. have been the sole Canadian distributers for this metal.

Roy M. Wolvin, president of the Dominion Steel Corporation, has returned from England, where he has been in conference with officials and others interested in the steel merger, but no immediate announcement will be made as to what has been decided regarding the early developments of the British Steel Corporation. Regarding the Dominion Steel Corporation's connection with the proposed merger the president remarked: "Matters have not yet reached a point where any definite statement affecting the affairs of the company can be made."

INTERESTING BOOK

The Taylor Instrument Co., Rochester, N.Y., have issued a very attractive January issue of The Tycos-Rochester. This is a little book devoted to things scientific, and, of course, deals more or less with Tyco equipment. It proves interesting reading, however, apart from its trade flavor.

A Description of a New Reversing Turbine

An 8-inch Model of This Turbine Has Been Tested Out by Prony Brake and Also in Driving a Forced Draught Fan, and Gave Good Results

THE present invention relates to improvements in a steam turbine and the main object is to provide a device of this character whereby a steam supply will be automatically regulated or cut off. A further object is to provide a turbine of simple design and particularly cheap of construction. Another object of the invention is to provide means whereby a steam chamber is provided with an eccentrically disposed drum thereby allowing for steam expansion, said drum being provided with a central rotating paddle which is slidably mounted in said drum.

The invention will be better understood with the following accompanying drawings, in which:

Fig. 1 is a side elevation of the turbine, the upper half portion being shown in a longitudinal section. Fig. 2 is a cross section view on line A-A of Fig. 1. Fig. 3 is a front elevation of the steam supply controlling device. Fig. 4 is a longitudinal section view on line B-B of figure three (3). Fig. 5 is a cross section view through the eccentrically mounted drum.

Like numerals of reference indicate corresponding parts.

In the drawing, Part 1 indicates the base and Part 2 is a circular casing having at one side thereof an opening (Part 3) closed by a plug. Parts 4, 5 and 6 are outlet and inlet steam passages provided in the sides of said casing, said passages communicating at one end with the interior of said casing and Part 2 at their other end with a circular valve casing, Part 7 which is preferably integral with said casing (Part 2) at each open end of said casing (2) are cover plates. Parts No. 8 and 9 which are suitably secured thereto by means of the bolt (Part 10). Each of the said cover plates No. 8 and 9 are provided with corresponding eccentrically disposed openings (Parts 11 and general bearing No. 12) in which is rotatably mounted the cross shaft Part 13. Rigidly secured on said cross shaft, Part 13, is a drum (Part 14) which is preferably of same width of said casting (Part 2) and is provided with a central slot (Part 15) which projects therethrough and is adapted to register with the slot (Part 16) in the shaft (Part 13). The said drum (Part 14) may be provided with a plurality of longitudinal packing strips (Part 17) which are provided to form a staunch friction joint between said drum and portion of said casing 2.

The drum (14) being eccentrically mounted in relation to the casing Fig. 2. forms a steam expanding chamber (18) which is adapted to communicate on each side of said drum with the outlet and inlet passages (5 and 6).

Movably mounted within said slots 15 and 16, in the drum and cross shafts is a rectangular blade (19) which is provided with curved ends adapted to be in continuous contact with the inner circumference of said casing (2), said blade being provided with a plurality of friction members (20) mounted in suitable recesses and so arranged as to contact with the side of the casing or the inner sides of the slots (15 and 16) by means of the spiral springs (21) which are enclosed in suitable recesses.

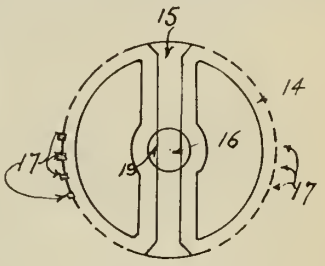


Fig. 5.

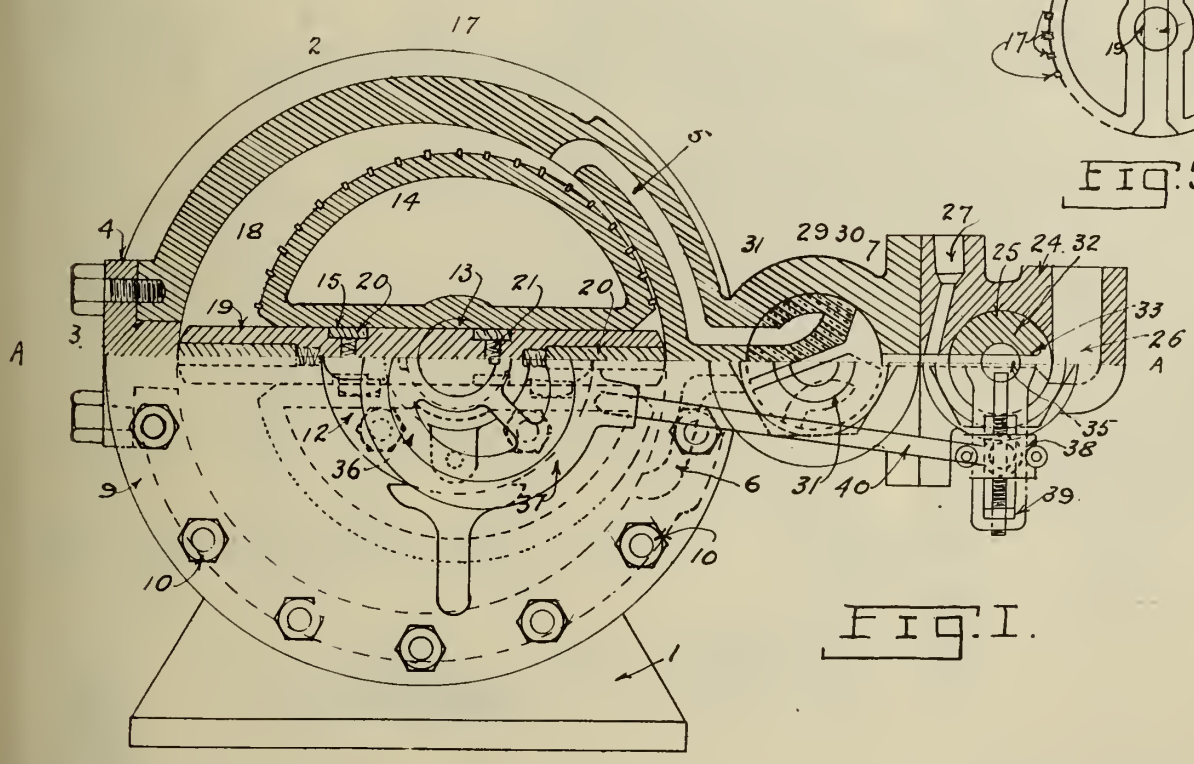

Fig. 1.

The valve recess (7) is provided with a passage (22) adapted to register with the passage (23) provided in the valve casing (24) which is suitably secured to the casing (Fig. 2) and 25 is a circular valve casing provided with the steam inlet (26) to which is preferably connected the steam supply pipe.

Intermediate of said valve casings 7 and 25, is a hole 27, adapted to communicate with the passage 22 and which may be used as an independent steam inlet when suitably connected to the steam supply pipe. The valve casing (7) is also provided with an exhaust opening

28 and 29 is a circular valve member rotatably mounted in said casing (7) and provided with a central passage (30) of a funnel shape at one end thereof which is adapted to register with the passage 22 and one of the passages 5 or 6 at the other end and 31 are exhaust passages provided on each side of said central passages and which are adapted to communicate with one of the passages 5 or 6 and the exhaust port or opening 28.

In the valve casing 25 is rotatably mounted a valve member 32 having a central passage (33) which is adapted to register with the passage 22 and steam inlet 26. The valve members 29 and 32 are preferably provided with outwardly projecting stems 34 and 35, the stem 34 is preferably manually operated by any suitable means, while the stem 35 is automatically operated by a cam (36) which is rigidly secured on one end of the shaft (13) and on which cam is slidably mounted a sleeve (37) which is operatively connected to the adjustable member 38 slidably mounted on the frame 39 by the connecting arm 40. The frame 39 is rigidly mounted on the stem 35 and 41 is a threaded pin having a cross head or handle 42 adapted to adjust the slidable member 38.

In the operation of the invention, the steam enters through the inlet 26, passes through the passage 33 in the valve 32, the passage 23 which communicates with the funnel shaped passage 30 and one of the passages 5 or 6.

Steam enters the chamber 18 in the chamber 2 which is so divided as to provide for the proper expansion of the steam at the same time causing the rectangular blade 19 slidably mounted in the drum 14 to revolve, until it passes the exhaust passage provided in said chamber (2).

In the drawings, the exhaust passage 5 registers with the exhaust port 31 provided in the valve 29 and the exhaust steam passes through the said 31 and enters the steam outlet 28 provided at the end of said valve casing (7). To reverse the turbine the stem 34 may be operated.

When the rectangular blade 19 has reached a predetermined point the steam supply through the inlet (26) is automatically cut off by the valve (32), which is operated by the cam (36), provided on the shaft 13.

It will readily be understood that the intermittent cutting off of the steam is regulated by screwing or unscrewing the threaded pin (41), which distances or approaches the slidable member 38, on which is pivotably secured the connecting rod (40), secured on a cam sleeve (37).

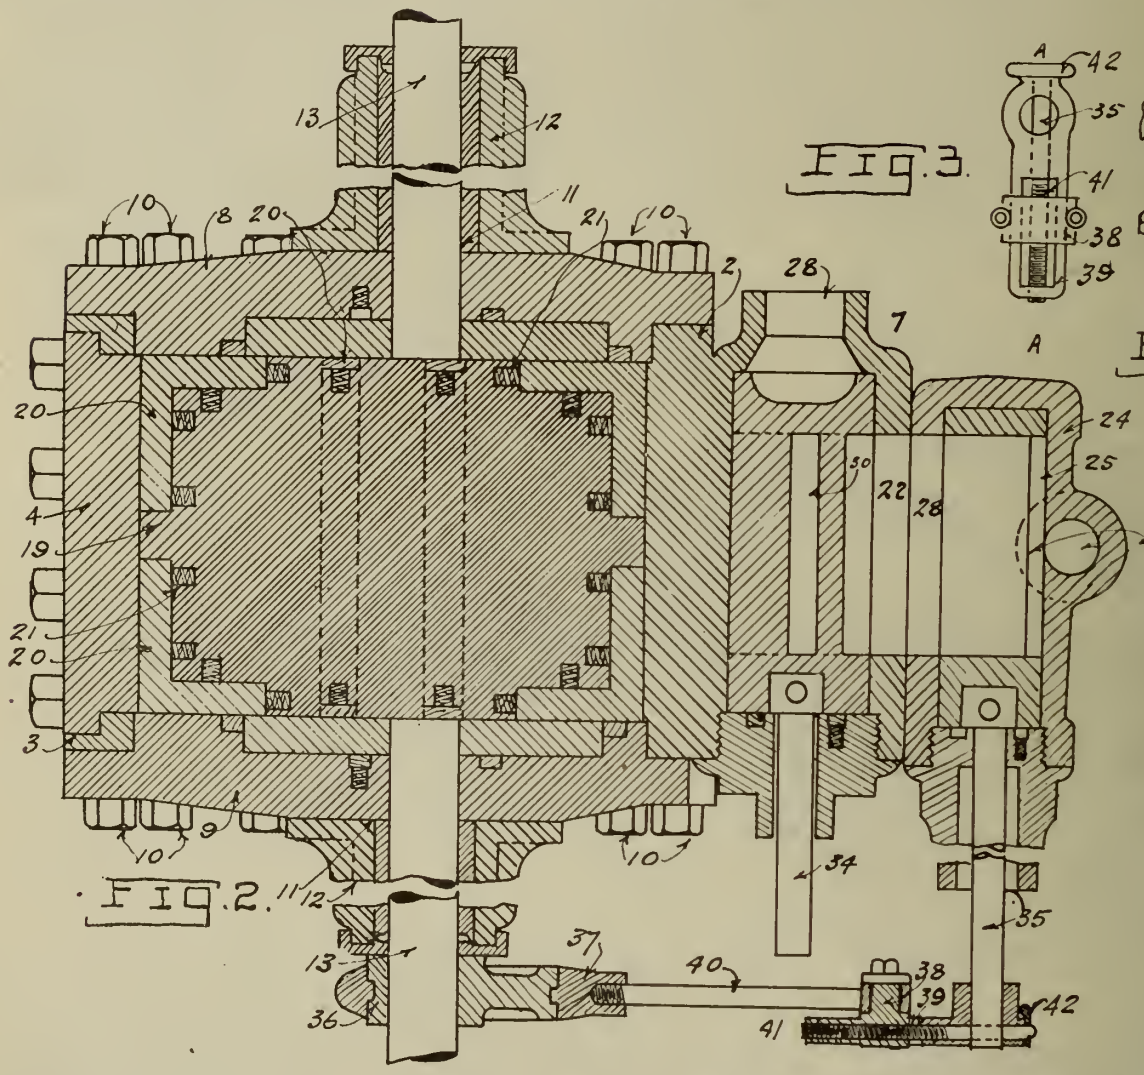

Fig. 2.

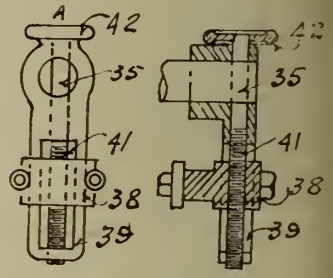

Fig. 3.

Fig. 4.

What I Claim As My Invention Is:

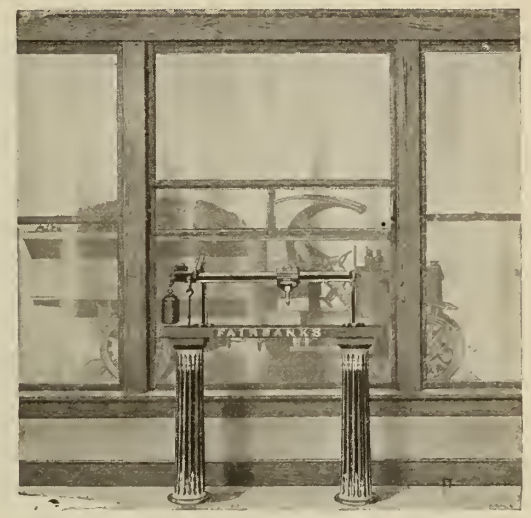
1. A turbine comprising a main ca ing, having an inlet and outlet port, rotary drum eccentrically disposed wit in said casing, rotating blade adapted contact at each end with inner circu ference of said casing and adapted to r tate said drum substantially as describ

2. A turbine comprising a main ca ing having inlet and outlet ports, a sha eccentrically journalled in the side said casing, a drum centrally mount on said shaft and adapted to provide friction contact with one side of sai casing, a slot provided centrally throug said drum and shaft and an operatin blade mounted on said slot and adapte to contact at each end with the inn circumference of said casing substan tially as described.

3. A turbine comprising a main cas ing having an inlet and outlet port, valve adapted to contact said ports, rotating drum eccentrically mounte within said casing operating blade con tacting at each end with the inner ci cumference of said casing and adapte to rotate said drum and means whereb said valve may be opened or closed auto matically at a predetermined time, thu

(Continued on page 40)

Fuel Consumption Statistics Depend On Accurate Weighing



Consistent accuracy in the weighing of coal is a necessity to the modern power house since it is the basis of all fuel consumption records.

Fairbanks Scales

are sturdily built to give unfailing, reliable service under the most severe power house conditions. The illustration below shows the strength and simplicity of the wagon scale parts.

Special Fairbanks Scales can be adapted to special situations and extension levers can be provided to carry beam up to 20 feet from platform of scale, placing it in an office or elsewhere at a price proportionate to the distance.

There is a Fairbanks Scale for every purpose. Write to our nearest branch for any information you require.

A NEW TURBINE

(Continued from page 38)

limiting the steam supply to said casing substantially as described.

4. A turbine comprising a main casing having an inlet and outlet ports, a valve adapted to control said ports, a rotating drum eccentrically mounted within said casing, a blade contacting at each end with the inner circumference of said casing and adapted to rotate in conjunction with said drum, means whereby said valve may be automatically opened or closed at the predetermined time to limit the steam supply to said casing and means to adjust said valve substantially as described.

5. A turbine comprising a main casing having an inlet and outlet ports, a valve casing adjacent said main casing, a passage communicating at one end with each of said ports and at the other end with the said valve casing, and said valve casing having an exhaust port and an inlet port, a rotary valve mounted in said valve casing provided with a steam inlet and steam outlet adapted to register with the passage communicating with said valve casing, a steam supply valve casing, a passage adapted to connect the steam inlet in the aforesaid valve casing to said steam supply valve casing, means to supply steam to said valve casing, a rotary valve member mounted in said casing, a rotating drum eccentrically mounted in said casing, a movable operating blade contacting at each end with the inner circumference of said casing and adapted to rotate said drum, and means whereby said steam supply valve may be opened or closed automatically at predetermined intervals to limit a steam supply to said casing substantially as described.

6. A turbine comprising a main casing having an inlet and outlet ports, a valve adapted to contact said ports, a shaft eccentrically journalled in the sides of said casing, a rotating drum mounted on said shaft, an operating blade adapted to project through said drum and contacting at each end with the inner circumference of said casing, a cam mounted at one end of said shaft adapted to revolve said valve and means to adjust the time intervals between the opening and closing of said valve substantially as described.

This model of steam reversing turbine was in operation in a small way, an 8 in. model, and was tried last fall, on November 24, at Levis, Quebec, at which time it developed 11.7 B.h.p., but this turbine shows to a better advantage when worked with vacuum and will develop more power. As I said before, it was tried with only 90 pounds pressure and gave the above result. It turned 600 r.p.m. with a load of 27½ pounds at the end of a 28 inch lever. It was also tried in another place to run a fan on board a vessel (Howden System Draft), to take the place of an engine 4½ inches by 7 inches. At another place it was installed to run a dynamo for 64 lamps and in all of the cases it gave better satisfaction than the engines did before, and besides was run at a great economy over the cost of running the engines.

MADE ADVANCES AFTER CLOSE STUDY

John J. Main Was Inventor of Note—Passed Away in Toronto Recently

John J. Main, inventor of the Heine boiler, and one of the outstanding figures in Canadian foundry circles, died at his home, 40 Prince Arthur Avenue. He had been ill a long time, and death folloewd a stroke, the fifth of its kind.

Mr. Main was born on the island of Jersey 70 years ago. He came to Canada as a young man, and for years worked at his trade as a boilermaker. It was the invention of the Heine boiler which gave him his real start in life. He became connected with the Polson Iron Works, rose rapidly, and when he retired three or four years ago was vice-president and general manager.

During the war Mr. Main served on the Imperial Munitions Board. Free of charge, he turned over to the military authorities his patents on boilers fed with crude oil, which were used extensively in many branches of the service.

Mr. Main was president of the Canadian Incinerator Company, president of the Policy Holders' Mutual Life Insurance Company, and a director of the Dominion Radiator Company. He was superintendent of the Doty Engine Company, John Inglis & Sons and the Bertram Engine Works at various times during his career.

OVERHEATING ALUMINIUM

While it is important to maintain a low-pouring temperature for casting aluminium alloys, it is equally important to avoid overheating the metal in the furnace charges. Doubtless some advantage is gained when overheated melts are allowed to cool to the correct pouring temperature, and part of the danger of overheating is minimized by so doing. Nevertheless, continues the Engineer, for aluminium, overheating is very objectionable because of the rate of dissolution of iron from cast iron melting pots and of the reduction of silica from clay crucibles, as well as absorption of gases from the local atmosphere. For molten metals, the absorption of gases increases with rising temperature, this being possibly due to the fact that metals form loose compounds with hydrogen and nitrogen. The absorbed gases are often held by the metal until solidification starts, when they are liberated and cause unsoundness. Hence an overheated melt would contain more absorbed gases than one not overheated, and it would be expected that castings poured from the former would be more unsound than those poured from the latter.

Switzerland is one of the principal producers of aluminium. In 1918 this country exported 10,500 tons of raw aluminum, to a value of 51,000,000f. To the figures stated must be added 2,000,000f. of bar and sheet aluminium, 6,500,000f. of technical appliances, and 3,200,000f. of other articles in aluminium. With the end of the war in 1919 the export of aluminium technical articles fell off, while that of household items was doubled. The latter exports rose to a value of 6,200,000f., of which one-fourth went to Italy and one-fifth to France.

GIANT ELECTRIC POWER STATION

The new electric power station at Glasgow, Scotland, takes rank as one of the largest in the country. It is designed for an ultimate capacity of over a quarter of a million horse power, and each generating unit—of which there are five in the first half of the station recently completed—will be of 24,000 horsepower. Each boiler is capable of producing 62,000 pounds of steam in an hour. All the latest labor-saving devices for loading coal into the bunkers, stoking the furnaces, and removing the ashes are installed, and a very high degree of economy in the production of electricity on a large scale is assured.

CATALOGUE ON CRANES

The Milwaukee Electric Crane and Manufacturing Company of Milwaukee, Wisconsin, has just issued a new 48-page catalogue illustrative and descriptive of their complete line of cranes. Much valuable information, the result of twenty-five years of active experience in the designing and building of hoisting machinery for shops, foundries, steel plants, and other establishments, is incorporated in this book.

Those interested in electric cranes or hoists, and especially in the prevention of accidents, will find this book chuck full of interesting data. A section of the catalogue is devoted to the horizontal drilling and boring machine made by this company and which is especially suited for operating, at one setting, on pieces too long or bulky for the usual type of machine.

Leaflet 1160-A has just been issued by the Westinghouse Electric & Manufacturing Co., which illustrates and describes the features of the Type CS Squirrel-Cage Induction Motors of this company. These motors are constant speed, continuous rated from 2 horsepower to 200 horsepower, 2 and 3 phase with 25, 40, 50 and 60 cycle, and 110, 220, 440, 550 and 2,200 volts. In addition to the discussion on the motor and its parts, the Type A auto starter and the Type 815 motor starting switch for 10 horsepower motors and below are illustrated.

H. W. PETRIE LIMITED

New and Used Power Plant Equipment

Steel Tanks:
Any Capacity, any Purpose.

Automatic Engines:
Up to 450 H.P.

Steam Engines:
Slide Valve, High and Slow Speed Types.

Vertical Engines.

Our tremendous stock of power plant equipment enables us to always fill your requirements. Let us tell you about the equipment in which you are interested.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

TURNING MOMENT ON SHAFT

Question.—If an engine runs over and the crank is at 90 degrees from the head centre on the out stroke, what is the downward pressure on the guide? (2) What is the tangential pressure on the crank pin? (3) What is the thrust on the connecting rod? (4) What is the twisting effort on the crank shaft? The crank is 15 inches from centre of shaft to centre of pin. Connecting rod is 60 inches long. Diameter of piston 20 inches and pressure on piston 100 pounds. Friction and weight of parts to be neglected. Also please explain how blowing down a boiler will remove sediment that has collected on bottom of boiler.

Answer.—When the crank is at 90 degrees to the centre line the twisting effort on the shaft is at a maximum. The thrust on the connecting rod will be according to the angle it makes with centre line of engine, and the pressure on the guide will also be a maximum.

We have a piston area of $20\times20\times.7854$ and a pressure of 100 pounds per square inch, which gives a piston rod thrust of 31,416 pounds. The connecting rod is 60 inches and the crank 15 inches. Then the base of the triangle formed by crank rod and engine centre line will be $\sqrt{(60^2-15^2)} = 58.09$ inches and the thrust in the connecting rod will be $31,416 \times 58.09 \div 60 = 30,473.52$ pounds The pressure on the guide is the component of the load on the connecting rod perpendicular to the guide. That is, it is equal to the load on the crosshead rod multiplied by the height of the crank divided by length of rod, or $15\div60\times30,473=7,618.375$.

The tangential force is equal to the thrust in the rod when the crank is at 90 degrees. The twisting moment on the shaft is equal to thrust in the rod multiplied by length of crank. This question was dealt with in the issue of January 20 and a diagram illustrating the subject was given.

With regard to the sediment in the boiler, if this is hard and firmly attached to the shell, blowing down will not move it. When the scale or sediment is still soft or in solution the action of blowing down removes it by the scouring action taking place as the water rushes to the pipe. The same action can be observed in a bath tub when the plug is removed and the water only leaves by gravity.

A BOILER PROBLEM

Question.—I am firing a H. R. T. boiler and am burning "Mountain Park" (a slack soft coal) under it at the rate of 15 to 18 pounds per square foot of grate surface. I get good combustion and little smoke. I have a splendid draft and clean water in the boiler and when working hard the water in the glass raises and falls three inches within a few seconds. The boiler is used for heating a building and at low pressure five pounds is as high as needed. Is this boiler working beyond its economical capacity? Will you explain why if it is? Would I do better by using another boiler which is now lying idle and have slower combustion? If so can you tell me why, when I get good combustion with one? I have been told I am using more coal with one. Can you show me.

Yours truly,

K. P.

Answer.—With good draft and ordinary run of mine coal, the burning of 15 pounds of coal per square foot grate per hour is quite normal. Whether your boiler is being operated over its normal rating or not cannot be determined without knowing the size of the boiler, but generally speaking it is more economical to run one boiler at capacity or over than to run two boilers at considerably under capacity. You have in the latter case the loss due to infiltration of air, radiation loses and ashpit losses practically multiplied by two, besides having two fires to clean, with the loss attendant, which is naturally higher than with one. You should be able to judge by the quantity of water evaporated what results you are getting.

As to the fluctuation in water level, sudden demands for steam would cause that, though hardly to the extent you mention. If you have a very small steam space, sudden demands on the steam supply would cause a reduction of pressure, with a more violent ebullition of the water. This would cause severe fluctuations of water level. The kind of return system you have may have some effect on this.

SAFETY VALVE REPAIRS

Question.—I am operating a steam plant which was installed in 1903. There are two Jenckes boilers of 70 H.P. each and the safety valves are worn beyond regrinding. They are lever and weight valves of 3½ inches diameter. Can I get new inside parts for them, both stems and seats? They are iron body valves with brass inside parts and there is no maker's name on them. They are a combination valve having a steam pipe connection. Where would you advise sending them for repairs?

Answer.—The repairs necessary can be carried out at any machine shop. It is necessary to draw the brass seats from the body and then turn up new seats to take their place. The brass used should be hard, and free from blow holes. You may find it cheaper to scrap the whole outfit and fit spring loaded valves and this would be more satisfactory. You could probably use the same castings, depending on the construction. The only thing to be absolutely sure of is that there shall be no valve between boiler and safety valves.

SAVING BY HEATING FEED WATER

Question.—What is the saving of fuel by heating feed water?

Answer.—Approximately 1 per cent. for every 10 degrees of heat added to the water. It can be found by the formula

$$\frac{T-t}{H-t+L}\times 100 = \%\text{ saving of fuel.}$$

Where

T = temperature of water leaving heater.
t = original temperature of water.
H = heat of steam in the boiler.
L = latent heat of steam in the boiler.

This is, of course, based on the ratio of the difference between water entering and leaving heater, to the difference between water entering heater and total heat of steam. For instance, to take a simple case, take steam at atmospheric pressure, water entering heater at 60 degrees and leaving at 180 degrees.

Then

$$\frac{180-60}{212-60+966}\times 100$$

$$=\frac{120}{1178-60}\times 100$$

$$=\frac{120\times100}{1118}$$

$$=10.7\%$$

New Truths and Old Fallacies

Hardness of Alloys—*Continued*

The difference in the measurements of the sustaining powers, under pressure, between tin-base copper hardened metals, and lead base metals, free of copper, as shown by tests by the American Society for Testing Materials, is so slight that in some cases it is not more than the breadth of a hair.

In a test, made for us some years ago, Magnolia withstood 19 per cent. greater stress than a Genuine. This test loses some value because we do not know the brand or formula of the Genuine.

In 1912, Professor Robert H. Smith, an eminent mechanical engineer and authority, tested Magnolia against an imitation. In this case Magnolia withstood 16,980 pounds (7½ long tons) per square inch pressure before the test block collapsed. When it is considered that this was a small cylindrical shaped test block, unsupported on the sides to prevent spreading, it is evident how much heavier a strain Magnolia will bear without distortion, when supported in recesses of a shell, and what a large factor of safety it provides.

Professor John Goodman, an equally eminent mechanical engineer and authority, says of Magnolia: "My experience distinctly shows that the higher the pressure applied to a Magnolia Bearing, the better does the wearing surface become." He also says: "I ran a Magnolia bearing for some weeks under a pressure of two tons per square inch, at a surface velocity of 250 feet per minute; the temperature maintained at 130° Fahrenheit, by circulating water through the center of shaft. After the run the surface was perfect, although the lubrication had been meager, viz: 0.002 lbs. of oil on a pad weighing 0.002 lbs."

A Twenty Thousand Dollar Financial Expert

There are few men who could afford to have a personal financial expert to assist them in making the right kind of investments—the safe, sound investments that can be passed on as "an enduring" legacy.

And still fewer could afford to employ an expert who demanded a fee of $20,000 a year. But this is exactly what you have at your disposal—almost at your elbow—in the Investors' Inquiry Service of THE FINANCIAL POST.

Readers of THE FINANCIAL POST, through this service, can have the securities they are considering thoroughly investigated before spending a single cent. Men skilled in getting at the hidden factors and bed-rock facts that determine the value of stocks and bonds are at your service. Often securities many think are valuable are found to be unpromising, sometimes mere scraps of paper when the underlying features are uncovered.

It costs nothing to be sure. It may cost much—perhaps your hard-earned savings—to be sorry.

Readers of FINANCIAL POST are saved all this guesswork—this investing in the dark.

Whether you invest thousands or hundreds it will pay you to use this splendid service—free to all subscribers who make use of it.

THE FINANCIAL POST comes to you for one year—fifty-two issues on receipt of $5.00. Just attach a cheque or draft to the coupon.

THERMOMETER SCALES

Question. — I would like to know through your Power House magazine whether there are any other thermometer scales in use in the world besides the Centigrade and Fahrenheit. If so, please furnish names of them.

Answer. — The three thermometer scales are the Fahrenheit, Centigrade and Reaumur, but the first two are the ones in general use. The Reaumur scale starts at 0 freezing point, boiling point being at 80. The relation between Fahrenheit and Reaumur is as 180 : 80 or as 9 : 4 plus or minus 32 degrees.

A locomotive turn table, 92 feet long, was recently lifted and moved horizontally 1,600 ft. at Kansas in ten hours by means of a 100-ton wrecking crane and two railway flat trucks. The crane first lifted one end of the turn table and a cribbing was built underneath at about two-thirds of its length from the crane. The crane was then lowered away. This action raised the far end and a cribwork was built there. The crane gave another hoist and the first crib was heightened. By repeating this process the turn table was raised high enough to admit the trucks below far more quickly than could have been done with jacks. Once on the trucks the table was easily hauled by a locomotive to its new site.

LUBRICATION AND THE GERM PROCESS

The following is a synopsis of a paper on "Lubrication and the Germ Process," by Henry M. Wells and James E. Southcombe, M.Sc., read at the British Association meeting:

The authors draw attention that the modern view of lubrication on the physico-chemical side is the existence of a residual valency or affinity between the oil and the solid surfaces of the bearing and journal. The problem has, therefore, to be considered as a kind of intimate relationship between the oil and the metal. This is quite a different view to that held by investigators in the past, who thought that the property of "oiliness" so strongly manifested by fatty oils as compared with mineral oils resided in some particular physical characteristic of the oil itself. The modern point of view has been elaborated recently by a number of students of the subject.

The authors have discovered the reason why the fatty or fixed oils possess superior friction-reducing properties to that of mineral oils. They have shown that this is due essentially to the presence in fatty oils of minute quantities of free fatty acids, which are absent in the majority of mineral oils. In consequence of this discovery they have added small quantities (about 1 per cent.) of fatty mineral or organic acids, which are easily accessible and relatively cheap to hydrocarbon oils. The products so obtained possess remarkably low frictional co-efficients. As an example, the addition of 2 per cent. of common fatty acid to a mineral hydro-carbon oil reduces the coefficient of friction shown by this oil on a friction testing machine from 0.0084 to 0.0052—a diminution of 26 per cent.

By suitably choosing the type of fatty acid to be added to mineral oil, the behaviour of oils in the presence of water and other contaminating substances can be modified at will. It is also shown that the risk of metallic corrosion is even less with these oils than the usual compounded oils, because the latter frequently develops in working notable quantities of free acid.

The principle of making mineral lubricating oils possessing increased frictional properties by adding to mineral oils suitably chosen fatty acids in relatively minute amounts has been patented throughout the world, and has been somewhat fancifully called the "germ process," because the fatty acid is the germ of the idea.

The value of the process lies in that oils possessing friction-reducing properties much superior to mineral oils can be prepared at relatively little extra cost to mineral oils. Secondly, by this means an immense quantity of fatty oil suitable for the manufacture of margarine and other foodstuffs is liberated for the country's needs and substituted by a much smaller amount of commercial fatty acids, which are quite unsuitable for food and are more or less in the nature of a by-product.

Finally, it may enable the lubricating oil manufacturer to produce the highest class of friction-reducing oils from comparatively thin — therefore cheaper — mineral oils, and incidentally this may have the utmost significance to-day, when we are striving to foster and develop the mineral oil production of our own country and the Empire.

LOOK WHO'S GOT IT!

There is a growing suspicion that the newspaper reporters have not been interviewing the right parties!

—Des Moines "Register."

IT'S TIME TO DECIDE

what you are going to do about reducing the expense of operation in your boiler-room. The time has gone by when this costly department of your business can be permitted to spend from 10% to 50% more than it should for efficient power production. In most cases this waste has been due simply to neglect on the part of management busy with other and seemingly more important plans for production.

The time has come, however, when costs of operation again must be carefully scrutinized and every needless expense cut to the bone.

There is no department of your business where you can show better results than in your boiler-room.

VULCAN
Soot Cleaners

Many of the largest CENTRAL STATION PLANTS in the country use Vulcan Soot Cleaners to remove the soot and ash accumulations from their boilers. These plants SELL POWER, and they know what it means, in profits and losses, to keep their boilers clean.

Vulcan Soot Cleaners are installed within the boiler setting and operate mechanically. They will save from 4% to 8% of your fuel consumption over hand cleaning, besides doing away with the dirty, disagreeable, time-wasting, hand-cleaning job. With reasonable care and attention they will last indefinitely, and will always return a high profit upon their investment.

You may need other things in your boiler-room, but boiler improvement begins with soot cleaners.

"Spending $796 to Earn $1017.40!"

We have issued an analysis of the cost and earning power of a Vulcan Soot Cleaner, showing that on an average size boiler it will earn more than 127% on its investment. A copy of this analysis will be mailed cheerfully upon request, together with our Bulletin. (Please mention type of boilers in your plant).

We Jacked 37 Tons on These Jeffrey Roller Bushings Before They Distorted A Bit.

"You see the Jeffrey people give the Double Bushings of the Jeffrey Carrier a special heat treatment which gives them a hardness akin to glass that is practically immune to wear. But we wanted to be sure that these bushings had the right toughness and resilience to stand the 'gaff.'

"There's no proof so convincing as a practical test. When these bushings stood up without distortion with the gauge reading 37 tons, we were satisfied. Moreover, the ragged fracture shows that the initial toughness is preserved and increased.

"The second test was just as interesting as the first. They tried to gnaw through the outer walls with a sharp file—but nothing doing. It's almost as hard as glass, all right."

The Jeffrey Co. are putting out **Bulletin No. 210-4**, which describes the Carrier completely and tells of the practical tests they made before they were satisfied with the Reliability and Dependability of this Jeffrey Carrier. You'll never regret investing a stamp to write for it.

An Era of Saving
To Follow One of Waste

THE COPES
BOILER FEED REGULATOR

represents one of the smallest items in boiler plant investment. Its purchase price, cost of installation and maintenance expense are negligible when compared with many other items of power plant equipment.

Nevertheless it is one of the most influential factors in saving fuel and promoting the efficiency of labor. It increases the peak load capacity of a boiler plant, promotes safety, and reduces wear and tear on the equipment.

HOMESTEAD
Quarter-Turn Valves

Use Proves Their Value

When you put **Homestead** Valves up against the hardest services in your plant, then you realize their absolute safety, their strength and durability, that they are constructed to stand greater pressure than that for which they are recommended.

Homestead Valves close with a quarter-turn and remain tight without dripping or leaking. They open with a single quarter-turn of the lever.

Direct and unrestrained flow with simplicity and ease of operation are conspicuous Homestead features.

Elimination of waste and leakage soon pays for **Homestead** Valves.

You should adopt them without delay. Write for catalog.

Homestead Valve Mfg. Company

Good Times Just Ahead

PROSPERITY is within our reach in Canada.

All we need to have and to hold it is a sane, sure grasp on its simple elements.

They are Industry, Integrity, and Faith.

These are the cardinal virtues of human relations. They are the underpinnings of healthy, natural business life and the foundation of a wholesome social system.

They are the fountainhead from which Progress springs. A well-known business economist has called them the "Fundamentals of Prosperity."

Your purchases are an expression of Faith. They are evidence of your Industry. Make them confidently from business institutions of Integrity.

Buying is the backbone of prosperity. An active market means more employment, steadier earnings; benefits are passed around.

Wise spending gives stability to earning and for that reason is far-sighted thrift and sound economy.

The call of to-day is for cheerful thinking, willing working and constructive action by you—everybody—NOW.

To-morrow's change for the better will come about through the combined efforts of each and every one of us.

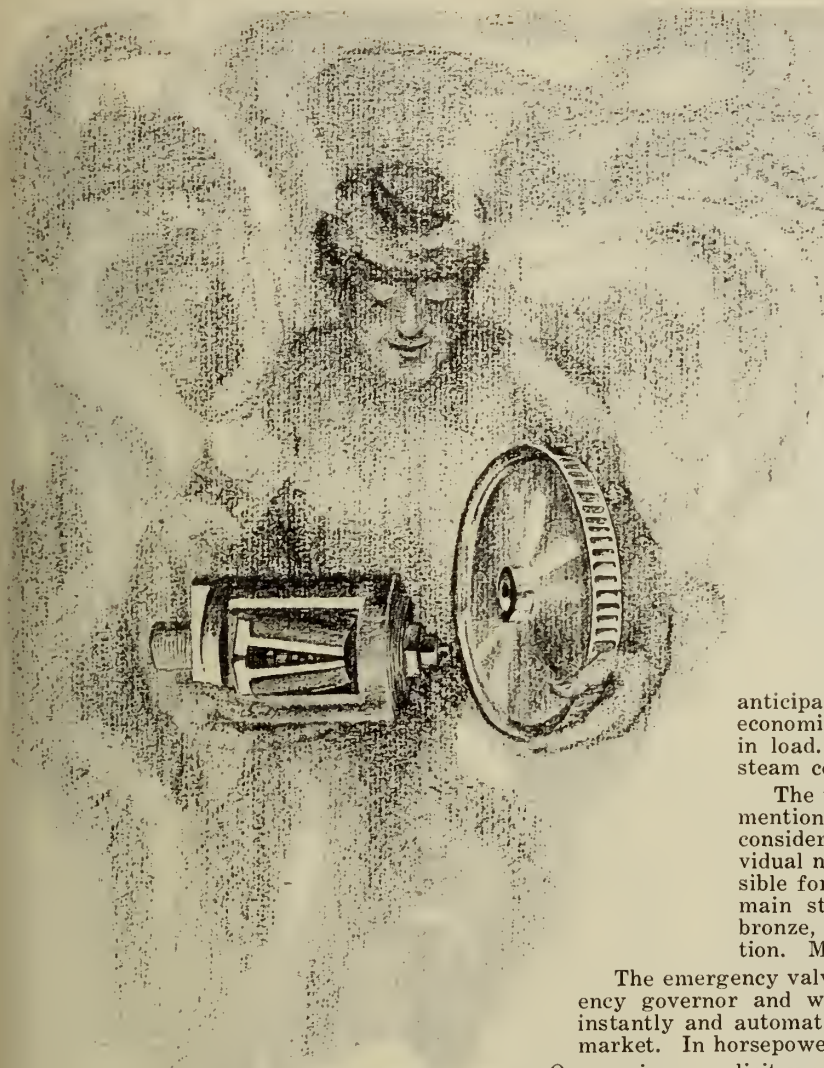
By sheer force of numbers and co-operation, by the high power of heart and mind, we can put Business on a firm, stable basis.

We can do this because all of the material factors making for better business are right.

Let us link our faith with industry, our vision with courage, and forge ahead.

Let's make an uncommon effort toward a common end—Good Times.

A message from the Associated Advertising Clubs of the World.



Sturtevant
(TRADE-MARK.)

TURBINES

Anticipate New Demands for Economy

Demands made to-day of turbines designed for driving fans, blowers, generators and pumps are more exacting than ever before, consequently turbines built to meet requirements of the past, cannot compete with those built for modern conditions.

Sturtevant Type 10 Turbine

anticipates these ever changing requirements and gives economical and dependable service regardless of the range in load. Continuous operation is assured with minimum steam consumption.

The nozzles and reverse buckets are features worthy of mention when the advantages of Sturtevant Turbines are considered. By simply closing a hand valve each individual nozzle can be cut out of service. This makes it possible for light loads to be carried without shutting off the main steam supply. The buckets are made from tobin bronze, carefully fitted and polished to reduce steam friction. Milled into the rim by our own patented process.

The emergency valve assures reliability. It is connected to an emergency governor and when a predetermined speed is exceeded, closes instantly and automatically. This turbine has been twelve years on the market. In horsepowers from one to five hundred.

Our engineers solicit your correspondence in regard to applying Sturtevant Turbines to your particular needs.

Send for catalog 256N for detailed description of construction.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS VACANT

ENGINEER QUALIFIED TO TAKE CHARGE of Saw Mill Power Plant; only competent man need apply; duties to commence immediately. Apply Box 24121, "Power House." (pfh)

WANTED AS ASSISTANT EDITOR, ON group of technical papers, live-wire mechanical engineer. Qualifications required are: Age, under 45, good education, certain amount of practical experience, ability to express ideas on paper, good mixer and aggressive worker. Splendid opportunity for the right man. State full particulars in first letter, mentioning present salary. Box 200, Power House.

EMPLOYMENT DESIRED

ENGINEER-MILLWRIGHT, 3rd CLASS, MARried. Wants position. References. Apply Box 201, Power House. (pfh)

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers. Corliss and all classes of stationary engines, compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St., Toronto.

MACHINIST WITH DRAUGHTING EXPERIence, wants work of any kind. N. Ryckman, No. 174372, 5 Foxley St., Toronto. Phone Parkdale 3254w. Mention "Power House." (pfh)

MECHANICAL ENGINEER, 29, FIRST-CLASS stationray engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House.

BELTING

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto. (p.f.h.)

WE HAVE A QUANTITY OF NEW RUBBER belting to sell at less than half price; will ship C.O.D., subject to inspection; new circular saws, good second-hand leather and rubber belting, wire cable, vises, chain blocks, garden hose, steam hose, rubber packing; send us your requirements; our quotations will surprise. Apply, mentioning "Power House," to The York Belting Co., 115 York St., Toronto, Ont. (p.f.h.)

EQUIPMENT

BOILER FOR SALE—CAPACITY 150 H.-P., horizontal tube, size 72" x 16' long; working pressure 110 lbs. steam; Government inspection certificate. Apply, mentioning "Power House," to the Steel Company of Canada, Ltd., Canada Works, Hamilton, Ont. (pfh)

STEEL TANKS, STACKS, PUMPS, CONDENSers, steam engines, boilers, heaters, transmission and elevating machinery, safes, vaults and vault doors; catalogues and specifications sent on request. Apply, mentioning "Power House," to The Goldie and McCulloch Co., Limited, Galt., Ont. (p.f.h.)

GRATE BARS

ALL STYLES TO ORDER PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House." (p.f.h.)

Like Paying a Thief to Rob You—

Just imagine, if you can, going out into the street and saying to a thief, "Dear, kind Mr. Thug, please rob me. And here is fifty dollars for doing the job." Can you see yourself doing it? Certainly not—

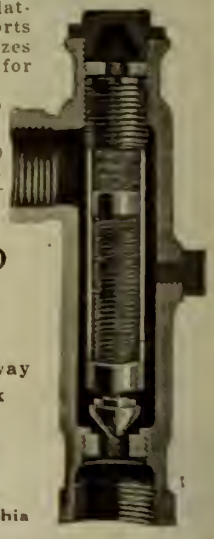
—and yet there are some concerns that pay good money for an old-fashioned "bucket" or "float" type steam trap that starts to rob them the minute it is installed! Robs them through inefficient operation by passing steam—by permitting condensate to collect and cool in large volume, thereby wasting valuable heat units by getting out of order and creating heavy repair bills.

Sensitive to a marvelous degree, the Sarco expansion element opens the valve and allows all condensate to drain off the minute it collects. No chance for it to get cool and waste heat units before being returned to the hot well.

Having no levers, floats, washers or other parts to get "out of whack" easily, it stays on duty year after year, without a cent's worth of repairs.

And—here is a feature you can't ignore—this highly efficient trap that saves you money after it is installed costs only one-third as much as the "bucket" or "float" type trap.

Installed in double-quick time on any line, without platforms, supports or pits. Sizes ⅜ to 3 in., for any given pressure up to 200 lbs.



Sold on 30 days' trial. Write for Catalog J-12.

Of Interest to Every Canadian

Number One of a Series of Advertisements

Efficient service is the keynote of membership of

Power House

—IN—

Canadian National Newspapers and Periodicals Association

—a highly constructive service—absolutely dependable and devoid of prejudice and personal bias. It means much to you!

The policies and principles back of this important service enable you to secure practical and impartial information of great value in business and in the home: and they assure a ready fund of literature of exceptionally high standard at all times.

To read the Association's Standards of Practice listed herewith is to understand what this Association means to you.

Standards of Practice

Canadian National Newspapers and Periodicals Association

THE Members of this Association shall dedicate their best efforts to the cause of business, and public service, and to this end shall pledge themselves:

1. To consider first the interests of the Subscriber.
2. To work for truth and honesty in all departments.
3. To eliminate, in so far as possible, their personal opinions from their news columns, but be leaders in thought in their editorial columns, and make their criticisms constructive.
4. To refuse to publish puffs, free reading notices, or paid write-ups, to keep their reading columns independent of advertising considerations, and to measure all news by the standard "Is it real news?"
5. To decline any advertisement which has a tendency to mislead, or which does not conform to business integrity.
6. To solicit subscriptions and advertising solely upon the merits of the publication.
7. To supply advertisers with full information regarding character and extent of circulation, including detailed circulation statements, subject to proper authentic verification.
8. To co-operate with all organizations and individuals engaged in creative advertising work.
9. To avoid unfair competition.
10. To determine what is the highest and largest function in the field which they serve and then to strive, in every legitimate way, to promote that function.

This is Number One of a series of advertisements regarding an Association that typifies thorough-going Canadian stability. Read the forthcoming advertisements in Magazines, and Agricultural, Business, Religious and Educational newspapers, and Technical newspapers.

BUILD YOUR NEXT BOILER FURNACE LINING LIKE THIS

With Betson's Plastic Fire Brick it is easy for anyone, even without experience. No special forms or tools are necessary to lay up a one-piece, jointless furnace lining that is air and gas tight and free from the destructive effects of gases getting back of the fire brick lining, or expansion and contraction. No separate fire brick, tiles or blocks, and no clay mortar joints to give way.

Write for informing pamphlet.

The ANDERSON
PRESSURE OIL FILTER

Look up your yearly oil consumption figures; consider the ever-increasing prices of oil and the fact that you can save at least one-half of every bill by the use of an Anderson Pressure Oil Filter.

By collecting the waste oil in drip pans, properly located beneath the engine or machinery, and running it through the Anderson Filter you cut your oil bills in half.

In the Anderson the used oil undergoes a cleansing treatment identical to that of the refiners. It comes from the Filter clean and suitable for use on the finest bearings.

The Anderson is an economy too great for you to overlook. Write to-day for catalog.

Look on page 50

"A voice roared out, hoarse, profane;--the Mate's voice: 'Thought you'd try it again, did you, you dashed beach-comber. I'll teach you, and when I find the dog that left that rope for you I'll give him a leaf out of the same book. You bloody waster! I'll teach you! I'll——!'"

This is an extract from Frank Packard's "Pawned," which commences in the February 15th issue of MACLEAN'S MAGAZINE.

At the period in the story that this is written the leading character is a beach-comber in the South Sea Islands.

Three months later, John Bruce is stretched at full length on a luxurious divan in the most sumptuous apartment of the Bayne-Miloy, New York's newest and most pretentious hostelry.

How had this wonderful metamorphosis been made? It is a mystifying, enthralling, intriguing story, the secret of which you can only get by reading every instalment of Frank Packard's wonderful yarn.

OTHER UNUSUAL FEATURES

"Are We Ashamed of Our Snow? No!"
By Charles Christopher Jenkins.
This tells the story of the conquering of the snow-drift problems by the railways of Canada.

"The Drama of Our Great Forests"
By Arthur Heming.
"Meeting of the Wild Men," filled to the brim and overflowing with forest-lore.

"Solons of the 80's"
By Col. Geo. H. Ham.
Some episodes of the 80's and 90's when he and his confreres were recording Canada's political history.

"Soldiers' Settlements Making Good"
By Agnes C. Laut.
The wonderful success which has met the work of the Soldiers' Settlement Board in the West.

"The Cross in the Sky"
By R. T. M. Scott.
A psychic story; simply, forcefully told, and tinged with war atmosphere.

"The Queer Toff in Number 13"
By Leslie Gordon Barnard.
A human story of a brilliant man who almost "pegged out" until a wonderful love drew him back.

"The City of Peril"
By Arthur Stringer.
The concluding instalment of this melodramatic serial by one of Canada's favorite authors.

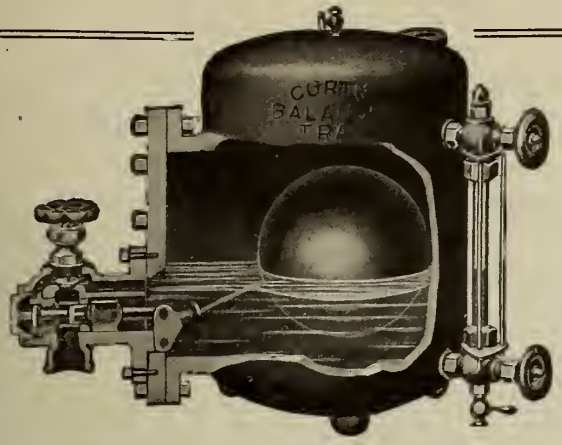
CURTIS Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lbs.

Write for 1921 Catalog of Curtis Engineering Specialties. Canadian funds are accepted at par at Montreal.

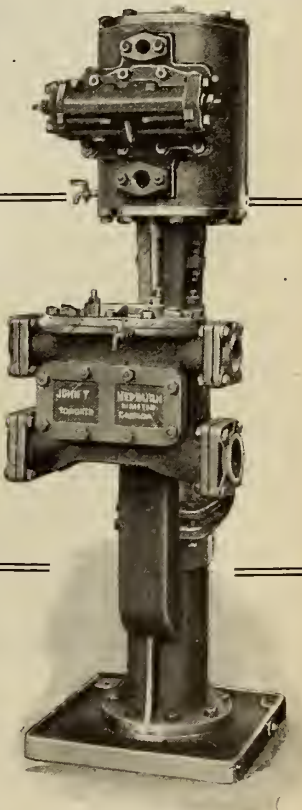
HEPBURN PUMPS



For High Pressure Boiler Feeding

A sturdy, compactly constructed, outside packed, Vertical Ram Feed Pump for Feeding Boilers carrying the highest steam pressures. The construction is simple with a minimum of parts. There are no Tappets or Levers. Every part is accessible. This type is of proved efficiency for pressures up to 200 lbs.

Write for particulars. We also manufacture Duplex Pumps, Vertical Engines, Compressors, and Hand and Electric Overhead Cranes for Power House service.

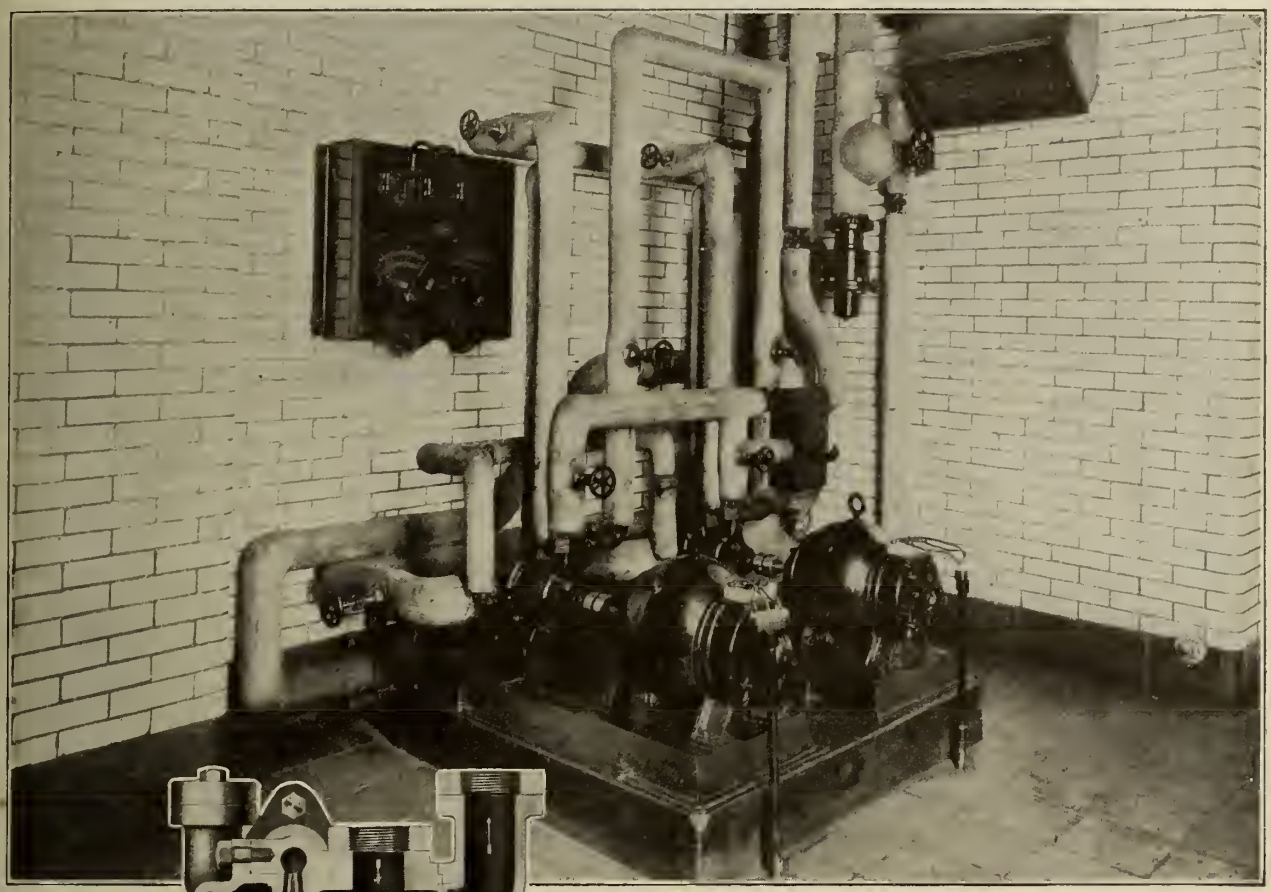
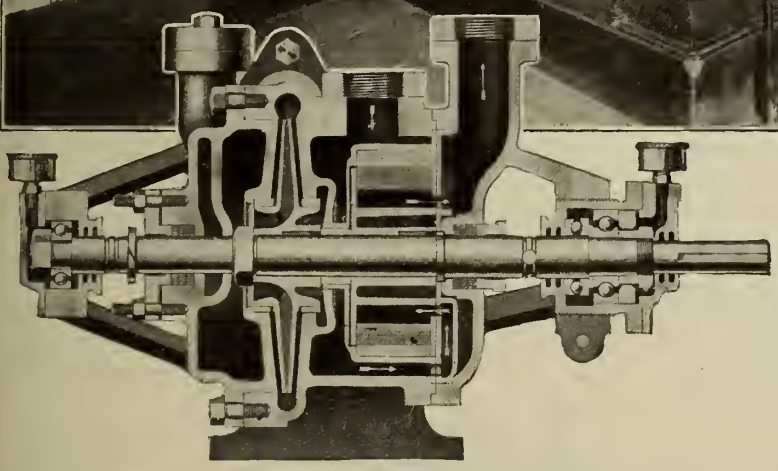
EFFICIENT HEATING *demands the* JENNINGS PUMP





Duplex "C" Unit, Automatic Operation

Combined capacity 52,000 sq. ft. direct radiation. Each pump has an air capacity of nineteen cubic feet per minute in addition to a water capacity of thirty-five gallons per minute.

The motors are only two horse power.

THE Jennings Pump consists of two independent turbine units, an air pump and a water pump. As each material is handled separately, the boiler pressure is against the water only. The air and vapor, approximately four-fifths of the volume handled, are delivered to atmosphere without back pressure. The saving in horse power is over fifty per cent.

Because of its compact design, this equipment can be installed in less than one-third the space necessary with other apparatus. All interior parts are bronze, supported on annular ball bearings mounted outside of casing. Moving parts revolve without contact.

There are many other reasons why the Jennings is being installed on practically all of the big jobs. Bulletin No. 8 gives them in detail. Write for it.

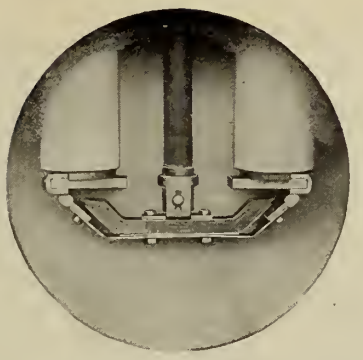
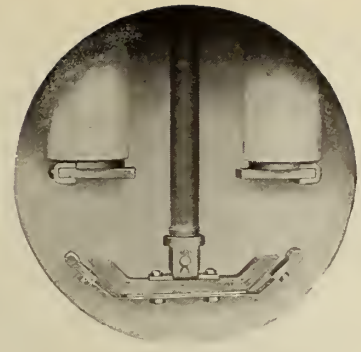
Closed



Arcing Tips Protecting Brush



Open

Circuit Protection Insured by Condit Oil Switch Construction

The laminated brush contacts give perfect wiping contact when closing the switch.

The auxiliary arcing tips finally break the circuit, avoiding arcing from main contacts.

Very liberal clearance is provided when the switch is fully opened.

The tank-per-pole arrangement of the Condit D13 Oil Switch illustrated below gives a high factor of safety.

This switch can be furnished in ratings up to 800 amperes at 15,000 volts, or 300 amperes at 27,000 volts.

Ask for information on the new Condit Double Tank construction, a most important new development in oil switch construction, giving greatly increased rupturing capacity.

Our nearest house will gladly furnish complete information on Condit Oil Switch construction and protection.

Growth of Utility Service Calls for Superheated Steam

UTILITY operation costs have increased. The growth of utility service has been insufficient to meet the necessities of the public and of industry. Expansion of utility service, while necessary, will involve additional power, and power will require fuel. A still further demand will be made on our diminishing fuel resources.

Only by the utmost conservation can expansion in service be realized. Superheated steam, correctly applied, plays a vital part in making possible both expansion and conservation, because for its first cost it renders higher net returns on the investment than any other means known or practised to obtain economy.

Elesco Superheaters are specified by discriminating engineers.

Send for Bulletins

THE SUPERHEATER COMPANY, LIMITED
TRANSPORTATION BUILDING,
MONTREAL
Works at SHERBROOKE, QUEBEC

Designing Engineers and Manufacturers of ELESCO Steam Superheaters and Pipe Coils for all Purposes.

Exciter and Night Lighting Sets

PARTICULARLY where the auxiliary turbine exhaust can be utilized in feed water heaters or for heating, drying and other purposes, the small, directly-connected De Laval steam-turbine-driven generating set is the most economical, as well as the most simple and reliable, unit that can be installed. It is not dependent upon the main generating units and little or no attention is required.

De Laval Turbo-Generators are made in all capacities, A. C. or D. C. In medium or large auxiliaries, speed-reducing gears are employed, so that the turbine can run at the best speed for efficiency, while still preserving the simplicity and reliability of moderate-speed generators.

15 Kw. Directly Connected Direct Current Generating Unit

If you will state your requirements we shall be glad to send appropriate literature, together with detailed information. Ask for Booklet C-100.

Worthington satisfies every power plant pumping need

IMMENSE shop facilities, standardized manufacturing plus over 81 years of designing, improving and manufacturing pumps and pumping machinery have resulted in apparatus of suitable design for every power plant pumping duty.

This broad range and varied choice of apparatus together with over 200,000,000 boiler horse power successfully satisfied since 1840 justifies specifying Worthington for power plant apparatus. The Worthington engineering corps always stand ready to co-operate in order to obtain greatest possible results from apparatus selected.

Morrison Steam Goods

"Every installation is a demonstration of merit."

The Tyranny of Prestige!

A reputation for dependable quality extending over half a century makes exacting demands. The reliable service to which Morrison Steam Specialties have accustomed their users would cause even the slightest variation of quality to become as noticeable as a bulge on a boiler. Thus does the tyranny of prestige become a guarantee of quality maintained.

Jenkins Valves

Valve Testing Operations in the Jenkins Plant

Tested!

There is no "maybe" about the serviceability of Jenkins Diamond Trade Marked Valves.

The test of Service as applied to every Jenkins Valve before it leaves the factory is a definite assurance of satisfactory performance even under unusually severe conditions.

And there is a Jenkins Valve for every class of service. Made of Brass, Iron, and Cast Steel in various types and sizes for steam, water, oil, gas, chemicals, etc.

You'll know the **genuine** Jenkins—the factory-tested valve—by the Diamond Trade Mark cast on the body.

COMPODISK

BRASS VALVES

"With the Composition Disc"

"Strong where others are weak"

"Outside Bonnet Construction"

The first improvement made in brass valve construction in generations past

Government Approved for 175 lbs. Steam Pressure

What the outside bonnet construction means—

It prevents corrosion of threads. It prevents spreading or enlarging bonnet end of body when tightening down bonnet to place. It eliminates all strains or stripping of threads. It makes a more compact valve, consequently a stronger one. The discs used in these valves will give long life under severe conditions. Every valve is fitted with packing gland and follower. Workmanship and finish unequalled anywhere.

A strictly high grade valve, at a reasonable price. Used by the best Engineers.

Showing Ease of Application

The life of a furnace is only as long as the life of its lining. Strength and permanency are yours when you use

PLIBRICO JOINTLESS FURNACE LINING

PLIBRICO assures fuel economy also. It is a plastic furnace lining, easily applied, which vitrifies into a one-piece, heat-resisting lining with NO joints. Used on new boiler settings or to patch up old settings.

PLIBRICO is shipped only in steel containers of distinctive appearance. Warehouse stocks carried in all principal cities. Write for book on Furnace Building.

JOINTLESS FIRE BRICK CO.
1130-1150 Clay St., Chicago, Ill.

The Dunham Radiator Trap consists of two major parts, a body and a cover holding the thermostatic disc. The man is tinning the disc before soldering it.

Sturdy Simplicity

Dunham Traps are made with extreme care and accuracy.

The result is *sturdy simplicity*. Nothing could be more simple than the two-piece Dunham Trap; and judging from service records of those in use since 1903, Dunham sturdiness is exceptional.

The Dunham Radiator Trap maintains a radiator at its maximum heating efficiency by permitting the passage of all air and water from the radiator and holding all steam within the radiator until it gives up its heat.

New Truths and Old Fallacies

Hardness of Alloys—*Continued*

Referring again to the test made by Professor Robert H. Smith, concerning the hardness of Magnolia, he said: "The longer the Magnolia bearing is used, and the more severe the duty imposed on it, the better becomes its condition."

When these tests were made by Professors Smith and Goodman, it is questionable whether either of them had considered the fusibility of alloys as affecting the values, but Professor Smith specifically says that he found Magnolia much superior to either Babbitt (Genuine) or Gun Metal (bronze).

The mention of bronze reminds the writer of an incident related to him by Mr. F. L. Johnson, once Associate Editor on "Power" and previously for many years a practical operating manager of large plants. When he was in charge of the Baltimore Copper Works a delay occurred in delivery of bronze bearings for the rolls. Without consulting him a supply of Magnolia was sent to tide over this critical period.

As there was no help for it, he poured the Magnolia bearings and then waited around for the expected trouble. To his great surprise the Magnolia lined bearings ran cool and far surpassed the bronze bearing in wear, and from that day he never used any metal on any bearings other than Magnolia, when he could get it.

Such demonstrations of Magnolia's capacity to sustain heavy loads and without injury, do not happen from chance. Magnolia is not only sufficiently hard, but is protected by its other qualities from heating and rapid wear on bearings, which are destructive to most babbitts.

Magnolia also favors adjustment to any inequalities of bearing or shaft, thereby distributing the load uniformly over the entire surface.

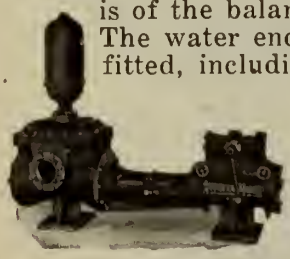
AMERICAN-MARSH PUMPS

SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.

The line also includes—
Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

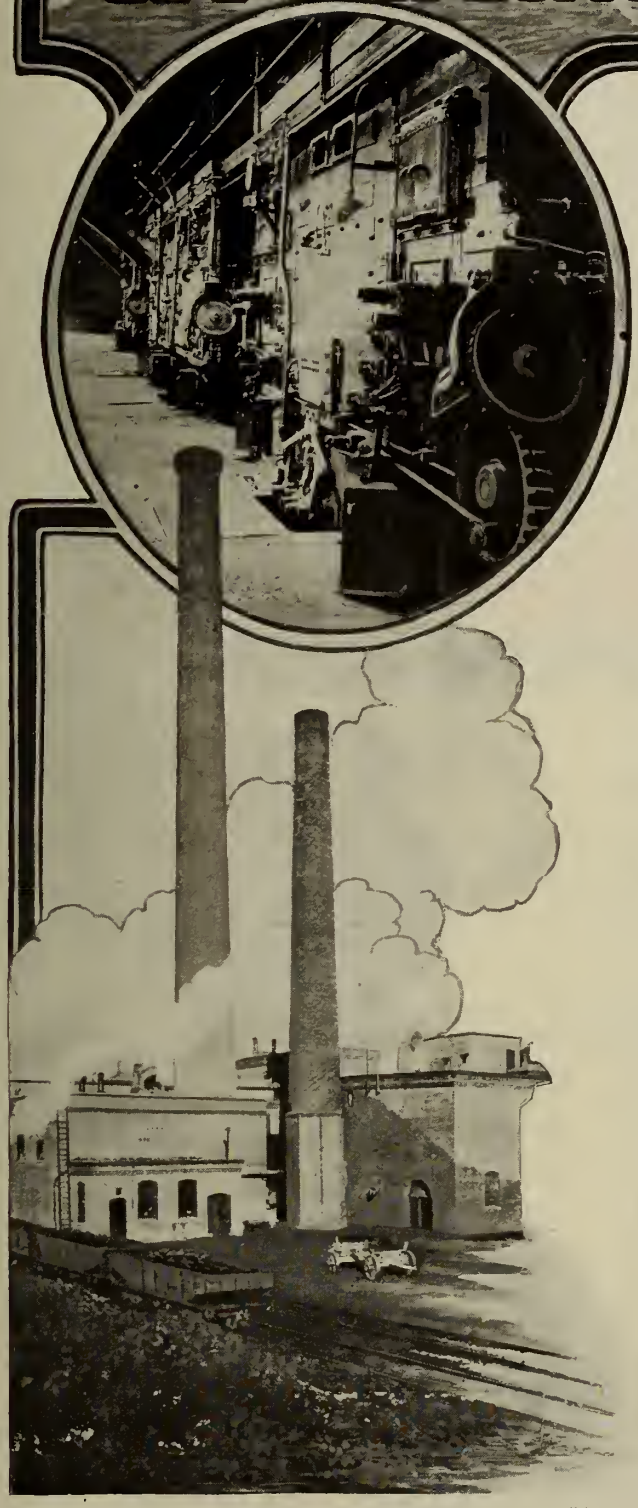
722 MURPHY FURNACES installed in 114 PAPER AND PULP MILLS



Pushing ahead from a single installation of one stoker under a 150 HP boiler in 1884, to 722 furnaces under boilers totalling over 200,000 HP today and installed by 114 different paper mills is the record of

MURPHY AUTOMATIC FURNACES

This fact has a significant meaning to every paper mill manager interested in power generation and gives you an idea of the success attained by the Murphy in this field.

Located as many paper mills are, in isolated places where breakdowns are more than ordinarily expensive, unfailing reliability is an essential factor.

Forty-four years of careful attention to Murphy design and development assures this reliability to an unusual degree.

In addition, the Murphy record for pounds of paper produced to coal used—for efficiency—for labor saving—for cleanliness—makes it the choice of such a large number of the leading paper mills of this country.

Let us send you our catalog M-2 It may lead the way to your saving money, men and fuel.

The Heart of Your Power Plant

is the boiler room and there's where all efforts to cut down factory costs must begin. And that is also the place and the reason why you should use

BETSON'S

REG. U.S. TRADE MARK PAT. OFF. PLASTIC FIRE BRICK

the one-piece furnace wall lining and brickless arch material.

Line your furnace with Betson's Plastic Fire-Brick instead of old-fashioned brickwork which invariably cracks and crumbles and lets in cold air. Then your walls will endure for years rather than a few months; and they'll be free from leaks and cracks, a seal against cooling currents of air.

Boiler arches, too, are readily constructed over simple, temporary sheet metal forms, and after a few hours' heating are all set for regular service. All in one-piece, no bricks to loosen and drop down, they hug the boiler closely as no brick arch ever could.

Betson's Plastic Fire-Brick assures an ideal furnace wall construction, which almost any workman can handle. It means practically a permanent freedom from furnace repairs. Look into it, lay in a supply of Betson's and prevent future boiler shut-downs.

Let us send you our instructive pamphlet about modern furnace wall construction as made possible by Betson's Plastic Fire-Brick. Just drop us a line to-day.

MONTREAL

FROM ARCTIC COLD TO SUPERHEAT

To withstand the wide variations of temperature and severe conditions of ice machine service, a special ammonia packing is necessary.

A packing failure in a plant having reserve compressors might merely result in ammonia loss, while in a smaller plant running at "peak load"—a shut-down due to inferior packing could result in a loss far exceeding the cost of a special high grade packing. Garlock Style No. 449 is a packing set specially designed for service on ammonia compressor rods—years of successful experience have proven this packing best suited for the work.

Packed in dust-proof cartons—extra sets can be kept in reserve—always in perfect condition for emergency use.

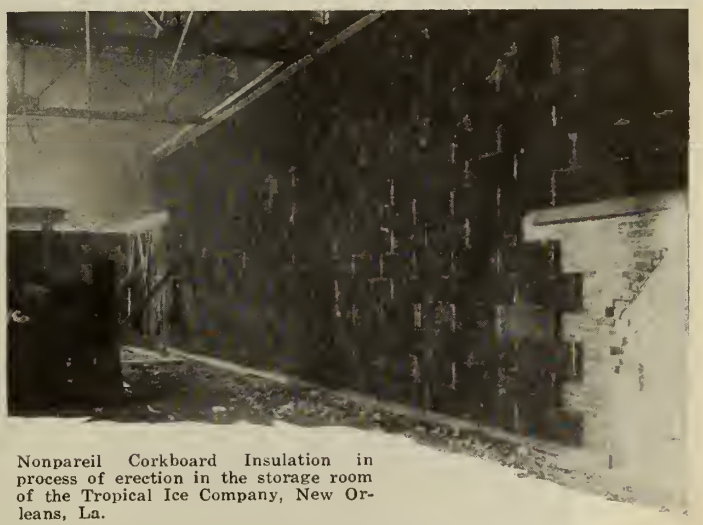
Does an Ice Storage Pay?

IT has been clearly demonstrated that the storage of manufactured ice **does** pay. How well it pays depends largely upon the cost of refrigerating the room. Since there is no heat in the product stored, practically all that refrigeration has to do is to remove the heat that leaks in through walls, floor and ceiling—or, in other words, through the insulation. Hence, the cost of operation and the efficiency of the room are conditioned almost entirely upon the heat retarding value and the durability of the insulating material.

For more than 20 years Nonpareil Corkboard has been repeatedly, continuously and convincingly demonstrating that in insulating value, in structural efficiency, and in permanent resistance to moisture, it is superior to any other type of cold storage insulation. When a sufficient thickness of Nonpareil Corkboard is properly installed, the minimum of refrigeration is required. And the remarkable durability of Nonpareil Corkboard is a guarantee that this efficiency is not temporary, but permanent.



Nonpareil Corkboard Insulation in process of erection in the storage room of the Tropical Ice Company, New Orleans, La.

The Company's Engineers can give you valuable information about the economy and construction of storage rooms for manufactured ice. They will be glad to consult with you without charge or obligation. Write for particulars and ask for a copy of "Nonpareil Corkboard Insulation"—152 pages of insulation facts.

TESTS OF HIGH PRESSURE GAUGE GLASS

Temperature—Not affected after 18 two-minute submersions in oil at 380 deg. F., then in water at 40 deg. F.

Erosion—No trace of erosion, and perfectly clear after live steam at 100 pounds pressure had passed through the glass for 96 hours.

Tensile Strength—Remained unbroken under hydraulic pressure of over 2,000 pounds per square inch for 2 minutes.

Service—Under continuous operating conditions with pressure of 225 pounds, performance equalled in every respect the best service ever obtained by any foreign glass.

DURABLA U.S.A. gauge glasses are now ready for distribution in all standard sizes and are sold under the DURABLA guarantee.

Investigation Leads to Conviction

Just why Sturtevant Steam Turbines have given continued satisfaction with minimum upkeep expense during the twelve years they have been on the market, will be fully understood after each detail described below has been studied carefully. The name

Sturtevant
(TRADE MARK)

on turbines assures economy and dependability in service.

This type of Sturtevant Turbine is especially fitted for driving fans, blowers, generators and pumps, with the minimum steam consumption, attention and repairs.

Only perfect workmanship, and the best obtainable materials are incorporated in their rugged construction.

Economy of operation is assured. Each nozzle is controlled by a hand valve on the outside of the casing and one or more may be separately closed when the turbine is to be operated continuously on a light load. Reversing buckets are cast together in segments, polished smoothly to reduce steam friction. If the speed of the machine gets beyond normal speed the emergency valve instantly and automatically closes.

Made in horsepowers from one to four hundred.

Thousands of satisfied users. Write for our catalogue 256 U with full information concerning the advantages of Sturtevant turbines.

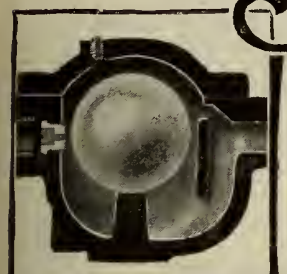
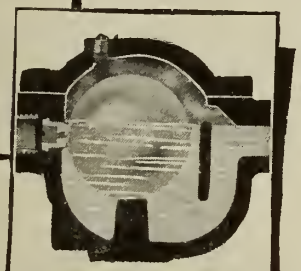
Trapped!

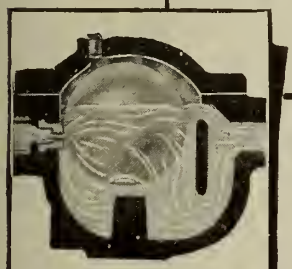
An educational movie showing how steam is trapped and water and air escape



The empty trap —ball resting on the post.

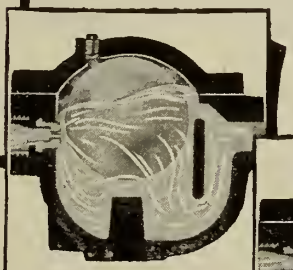


Water, steam and air enter trap.



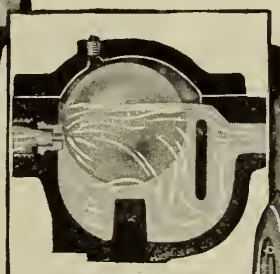
Water floats ball, carries it to outlet bushing and holds it there.

Water level rises, ball rises uncovering discharge orifice in bushing—water flows from trap.



The buoyant force of the water lifts the ball, pressure holds it to the bushing face. The ball actually rolls upwards on the face of the bushing.

Peak load—trap operating full capacity, discharge orifice entirely uncovered. At such periods the ball is swirled around and reseats itself when water level falls.



Water slug has been discharged. Water level lowered and trap operating normally and continuously, discharging water and air.

HERE'S the simplest steam trap made—the Johns-Manville Trap. It operates continuously and faithfully—without any fussy mechanism to get out of adjustment or order.

The unattached floating ball is the only moving part of the trap. Part of its surface acts as the valve, its radius as the lever arm and its weight as the counterweight. The forces that control its movement are the buoyant force of the liquid and the unbalanced pressure on the area of the discharge orifice.

Look at the illustrations which show clearly why the Johns-Manville Steam Trap is the most efficient and dependable trap you can buy.

Thousands of Johns-Manville Steam Traps in satisfactory service tell this same story.

The First True Diesel Made In Canada

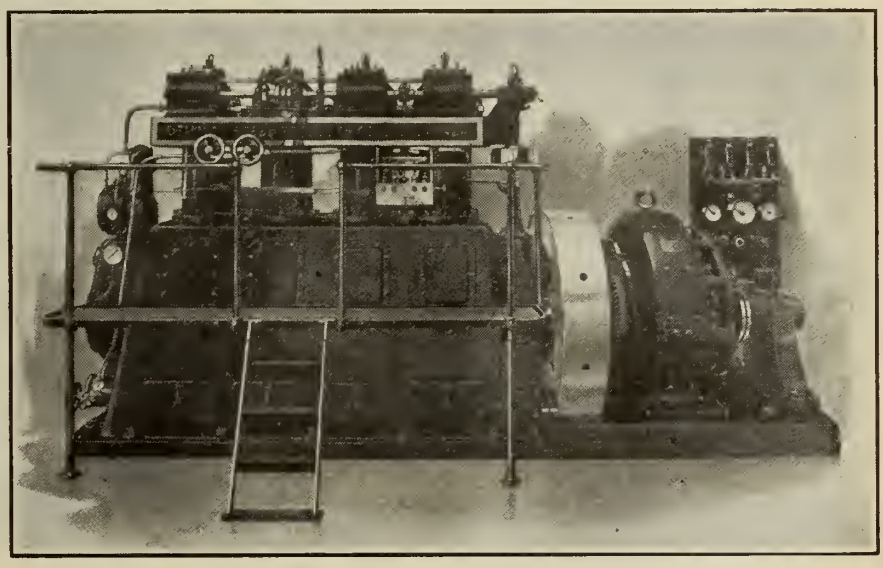
The History of the Diesel Engine—Two-Cycle, Four-Cycle, Solid Injection and Atomised Injection—General Description of the D. S. P. 100 B. H. P. 4-Cylinder Diesel

THOSE people who were interested in the exhibits shown in the Machinery Hall at the Toronto Exposition last year doubtless all stopped for a more or less interested look at a new kind of engine. This was the 125 h.p. Diesel exhibited by the Dominion Steel Products Co. of Brantford, and the first of its kind to be built in Canada. It is of the full or true Diesel type, as distinguished from the hot bulb or other surface ignition engines. This type of engine will doubtless have a great part in the developing of some of the outlying parts of our country, and every engineer should understand its principles and operating features.

The History of the Diesel

The Diesel engine should really be known as the Ackroyd Priestman engine, as the cycle it works on was first mooted by these two engineers in England, some years before Dr. Diesel took up the study of this principle. However, Dr. Diesel is usually conceded to be the man who first actually demonstrated its possibilities, and the basic patents were taken out by him in 1892. He built his first engine in 1893, and this was driven by a belt and did not do any work. What it did do, however, was to prove that oil could be ignited by the heat of compression of air, which is the main feature of the true Diesel engine. In the experimental engine, Dr. Diesel obtained a pressure of 1,350 pounds per square inch, and incidentally when the fuel was injected, the explosion that followed wrecked the engine. It almost resulted in the death of the inventor, but he rose from the ruins triumphant, for, even if the engine was demolished, the principle was established that the fuel could be ignited by means of the heat of compression.

Another engine was built, this time the compression being kept down to 500 pounds per square inch, and on this occasion the full cycle was obtained. Later another engine was built, with the cylinder water cooled, in 1896. Dr. Diesel sold his patents in 1897 for the sum of $1,500,000, so unlike many inventors, he actually realized the reward of his endeavor. His life ended in a tragic manner, he being lost at sea while journeying from Antwerp to Harwich in the year 1913.



D.S.P. H.C. OIL ENGINE. FOR CENTRAL STATION SERVICE.

The Cycle of Operation

The Diesel engine is built in two principle types, the two and four stroke cycle. These types are divided again into other modified classifications. In general, the two stroke cycle gets an ignition at each revolution, and the four stroke cycle receives an impulse every second revolution. In the two cycle type, on the inward or upward stroke of the piston, the products of combustion are discharged, and a fresh charge of air drawn in and compressed. At the top of the stroke the fuel is injected, and the down stroke is the working stroke. In this type the scavenging, or getting rid of the exhaust gases, is a difficult problem, and various means are employed to effect it. The simplest, and most generally used, is crank case compression. The piston descending on the downward stroke, compresses the air in the crank case to five or ten pounds, and this air sweeps through ports on one side of the cylinder when uncovered by the piston, and drives the gases out through a set of ports on the opposite side of the cylinder. Enough air is received on top of the piston to give the necessary compression. In other types the scavenging is done by a separate pump. Then there is the opposed piston type, in which the compression takes place between two pistons in one cylinder, and the working stroke is obtained by one piston ascending and the other descending. These work on three cranks, two of them being at 180 degrees to the other. The top piston is supplied with a crosshead, from which two connecting rods are connected to the two cranks at the outside, while the bottom piston is attached to the centre crank. When explosion or ignition takes place, the top piston pulls the two outer cranks up, while the centre crank is pushed down by the bottom piston. This type is known as the Junker, pronounced Yunker. Very often the scavenging in this type is done by a separate air compressor, instead of using the crank case compression.

The four cycle type is divided into solid injection and air spray injection.

In the solid injection type the fuel is injected by a fuel pump working at a pressure of 6,000 to 8,000 lbs., directly into the combustion chamber. In the air spray type, which is the one we are about to describe, the fuel is injected into a chamber containing compressed air at a pressure of about 1,000 lbs. per sq. inch, and shot into the combustion chamber as a finely atomized mixture of air and oil.

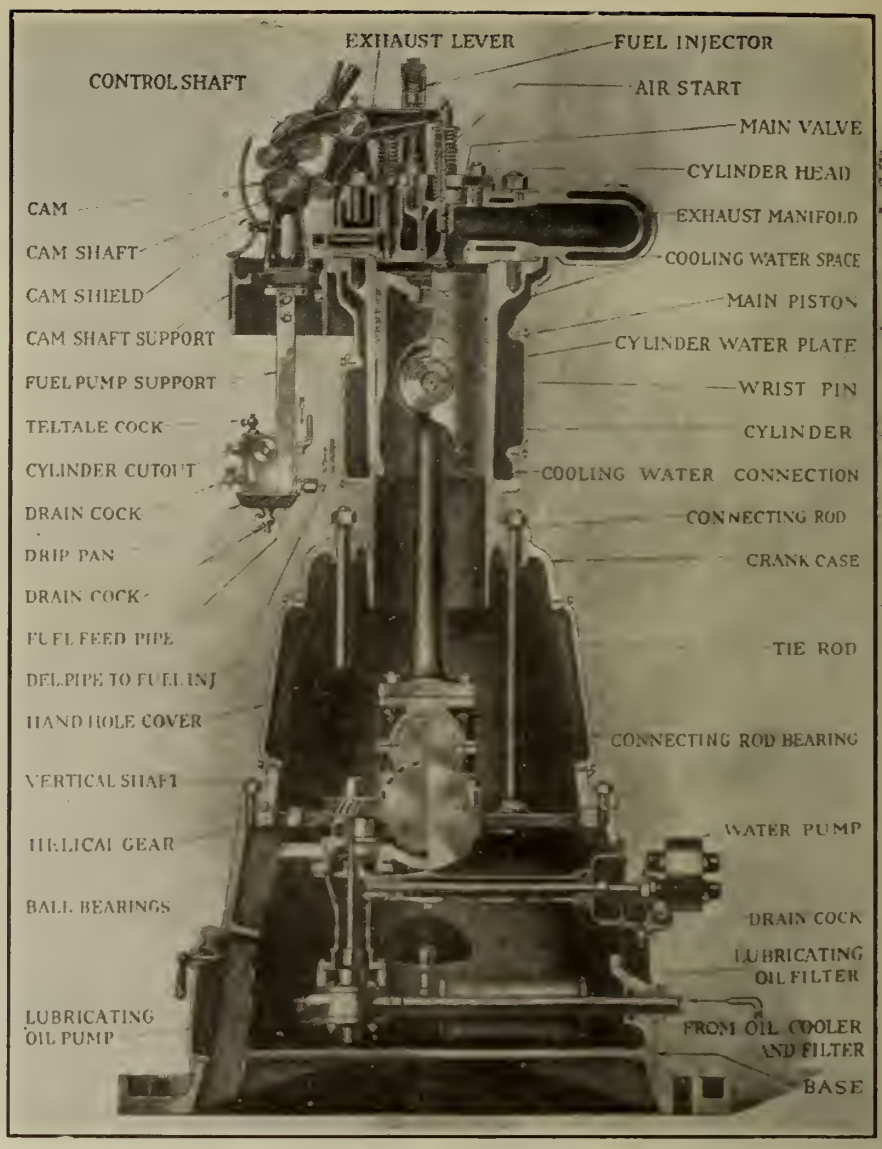
The two types have their different adherents, the solid injection school claiming that their method does away with the necessity of an air compressor steadily running, while the air spray school claim better combustion, which amply makes up for any supposed disadvantage from the use of a high-pressure air compressor.

The Four Cycle Type

In the four cycle type the first downward stroke, or outward stroke perhaps is a better way to put it, draws in a charge of pure air from the atmosphere, not the crank case. On the inward stroke this air is compressed to the required pressure, about 550 lbs., and at the top of the stroke the finely atomized fuel is injected by the air pressure from the air compressor delivery chamber. Ignition takes place at constant pressure, and the third stroke is the working stroke. On the fourth stroke the exhaust gases are discharged through a special exhaust valve and the cylinder is ready for the cycle to be repeated. The cycle may be described as suction, compression, expansion, and exhaust.

The D.S.P. Engine

The illustration herewith gives a good idea of the outside appearance of the engine, directly connected to a generator, for power and lighting service. This is exactly as the engine appears in the shop where it is now engaged in running a number of machines and overhead cranes. The engine is four-cylinder, four cycle, spray injection. On the end opposite the flywheel and generator is the air compressor for injecting the fuel, and supplying the air bottles, which are used for starting purposes. On the front can be seen the fuel pump. Both of these pieces of apparatus will be described fully later on. The engine operates on crude oil, with a specific gravity of about .865, or even higher, but with this specific gravity the oil will flow without heating in to the fuel pump. The efficiency of the engine is high, as it will deliver practically 30 per cent. of the fuel energy at the pulley as useful work. This is, of course, much bigger than with any type of steam prime mover, and is attained in the Diesel engine because the fuel combustion takes place in the same chamber that the work is done in. With the steam engine, the combustion takes place in a furnace, the heat is conveyed through the plates of the boiler into the water, and then carried

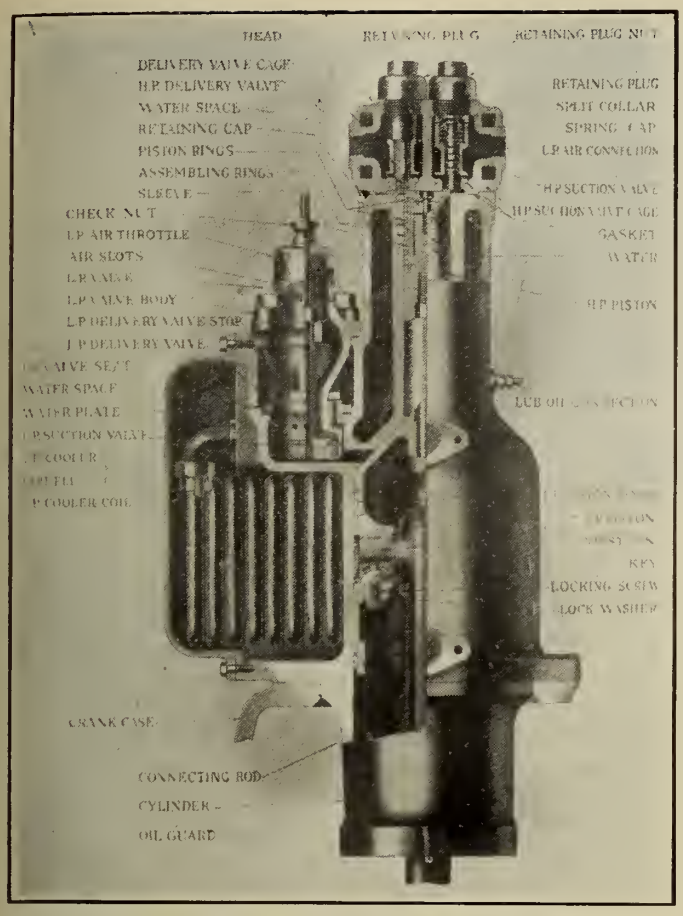


CROSS SECTION THROUGH CYLINDER.

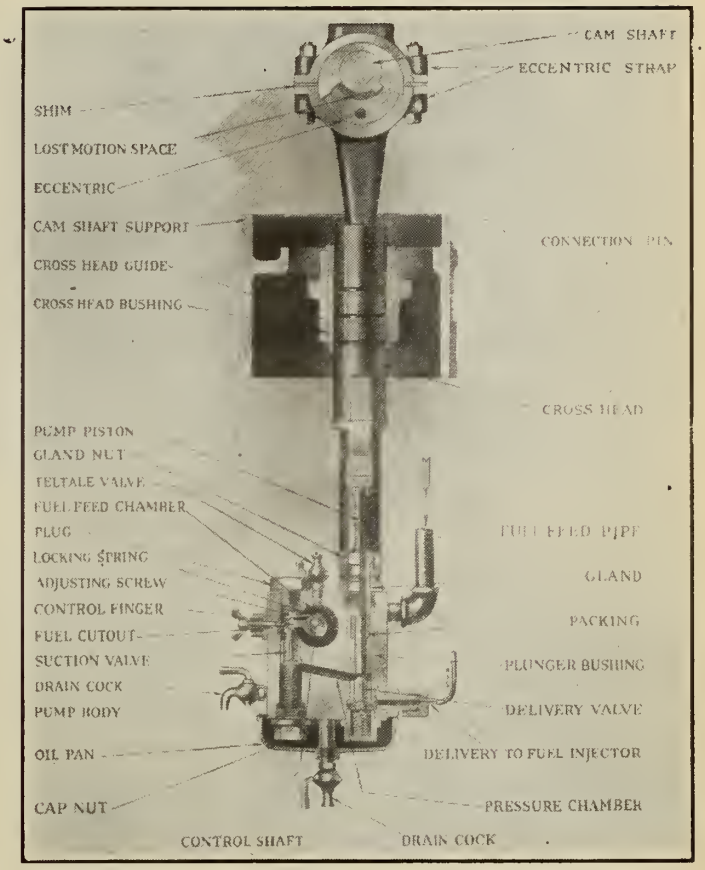
by the steam through piping into a cylinder or turbine casing, with many losses on the way due to radiation and friction.

In the engine we are dealing with compactness of design has been studied to good effect. It is necessary, of course, in an engine of this type to make provision for starting up. The method of starting is to admit compressed air to the cylinder to obtain the initial revolutions and compression. In order to do this it is necesary to have always a reserve of compresed air, and for this purpose bottles or flasks are provided, much like ammonia or oxygen cylinders. In most cases these are mounted on a wall convenient to the engine, but in the D.S.P. engine, provision has been made for carrying these bottles in the bedplate of the engine. This arrangement makes the engine absolutely self-contained, and ready to start the minute it is dropped down and secured to the foundation, and connection made to the fuel oil supply. The air is supplied to the bottles by the two stage air compressor situated on the end of the engine, and after the engine is started up this compressor supplies the air continually to the air injection valve for atomising the fuel. Such surplus air as may be delivered is diverted to the bottles.

The fuel pump is worked from a small crosshead, which is driven from a special eccentric mounted on the cam-shaft, which operates the valves. There are four plungers on this pump, one for each cylinder. The amount of fuel injected at each stroke is varied by a governor, which operates by holding the suction valve of the fuel pump open for a longer or shorter time, thus controlling the amount of fuel delivered per stroke. Holding the suction valve open, of course, is the same thing as shutting off the supply, and the speed of the engine is regulated very closely by this means. Each cylinder has the necessary valves for air start, fuel injection, and exhaust, and in addition to these, the two centre cylinders are supplied with air starting valves. These valves can be put on each cylinder if required, and the cylinder head is machined to receive them, but in practice it is only found necessary to use the two mentioned. These valves are all operated from a cam-shaft, driven by gearing from the main shaft. The



SECTION THROUGH AIR COMPRESSOR.



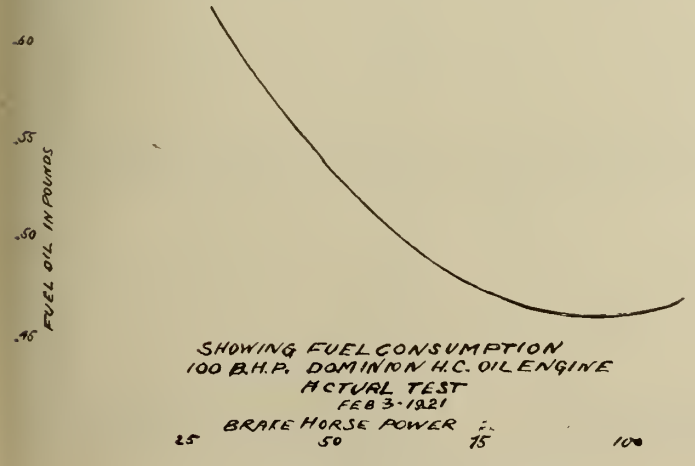
SECTION THROUGH FUEL PUMP.

cams operate levers, which open and shut the valves at the precise period of the stroke necessary to accomplish the various functions. The action of these cams is, of course, exactly the same as on a gas engine or a gasoline engine, with which most of us are familiar these days.

Starting the Engine

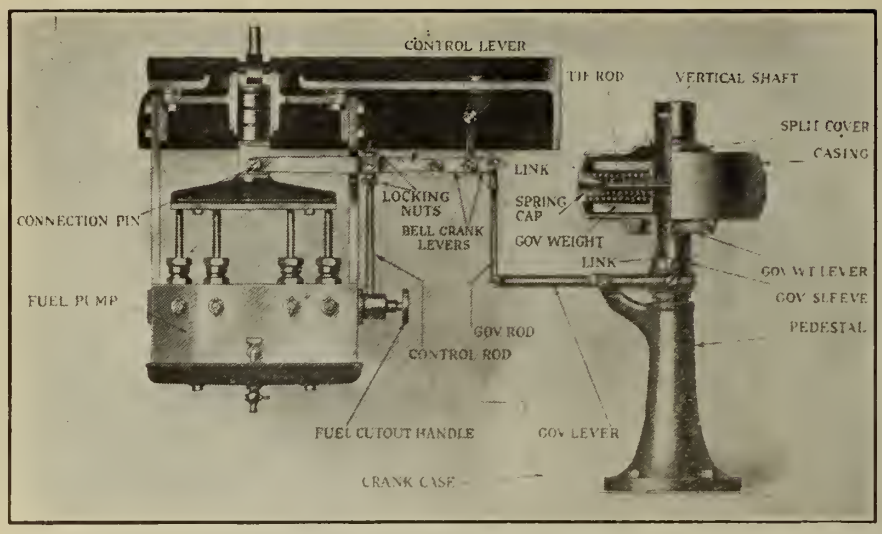
In starting the engine the following is about the method of procedure. The reserve air bottles will have been left when the engine shut down with a pressure of about 950 to 1,000 pounds, and will have, perhaps, dropped owing to the cooling of the air to about 800 lbs. or perhaps a little less. The operator first of all raises the relief valves of the cylinders by means of a special lever, which action releases the compression in the cylinders, and allows him to bar the engine round to the air start position. This position is, of course, that in which the air start valves on the two inside cylinders will be open for the admission of air. He then closes the relief valves again, and opens the valve from the air bottle. The engine immediately turns over, and the operator, who has previously seen that the fuel tank is full and ready for the day's work, opens the fuel control valve to give fuel to the pump, and closes off the air start valves by means of a control lever, which puts the air start lever into neutral position. This particular engine usually picks up after a couple of revolutions from dead cold. The operator comes in about ten minutes before starting time, looks at his fuel tank, gives a general look around the engine, and starts her up about five minutes to the hour, and is all ready with the current at the switchboard when the shop is ready to start.

Once started, the engine requires practically no attention. The air compressor draws in the air from the atmosphere, passes it over the element containing the air coming from the low pressure stage to the high pressure stage, thus cooling the latter, passes the air through its two stages, the final delivery pressure being from 900 to 1,100 lbs., according to the load being carried. This air is delivered to a chamber on top of the cylinder, and



FUEL OIL PER BRAKE HORSE POWER.

FUEL OIL PER KILOWATT.



THE GOVERNOR AND CONNECTIONS.

POINTS ON CONSTANT PRESSURE DIESEL ENGINE.

It can use high compression pressures as it does not compress a mixture.

The mixture is very lean and burns slowly and loss in cooling water is less.

Four gallons of cooling water per B.H.P. ample.

Perfect combustion due to complete atomizing and slow burning.

Oil of high flash point, thus cheap oil can be used.

Typical test data:—

Compression pressure per square inch, 510 lbs.

Mechanical efficiency, 82.5 lbs.

Fuel consumption per B.H.P., .45 lbs.

Cooling water Temp.—in, 46 deg. F.

Cooling water Temp.—out, 103 deg. F.

Exhaust gases, temperature, 600 deg. F.

Heat value of fuel, B.T.U., 19,000.

Specific gravity of fuel, B.T.U., 86.5.

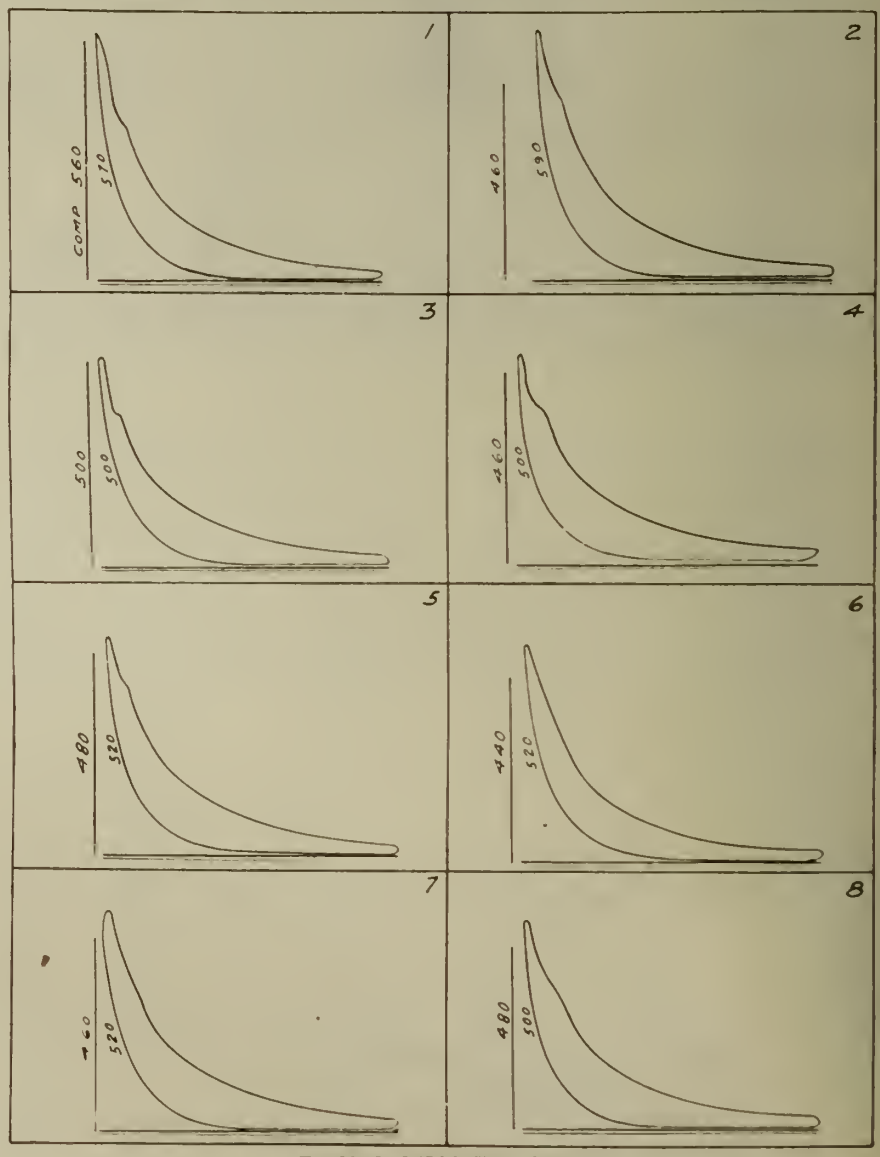
at the proper moment the fuel from the fuel pump is injected into this chamber and the valve from the chamber into the cylinder is opened, and the finely atomised spray of oil fuel injected. Ignition takes place without shock and combustion at practically constant pressure ensues, the gases expanding and driving out the piston. At a point just before the bottom of the working stroke is reached, the exhaust valve is opened, and held open throughout the return stroke discharging the exhaust gases. At about the top of the stroke, the cam closes the exhaust valve, and opens the air suction valve, and the cylinder is filled full of pure air. The valves are then all closed, while compression takes place on the fourth stroke, and at the end of this stroke ignition again occurs.

A pump situated in the base of the engine supplies oil under a pressure of ten to fifteen pounds to the crank pin, and through the connecting rod to the wrist pin, while special lubrication is supplied to the piston. The air compressor is lubricated by the oily spray generated in the crank pit by the passing of the cranks through the oil bath, and this is all the lubrication employed for the air compressor.

The accompanying illustration shows the typical indicator cards obtained from this engine, while the section cuts explain very clearly the working parts. Fuel consumption is shown by the curves illustrated here.

A representative of Power House had the opportunity recently of seeing this engine performing its daily task, and was impressed with its splendid performance under somewhat difficult circumstances. This engine was built with an ordinary sized flywheel, to drive a generator on fairly constant load. The work it is doing now is under very considerable variation of load, from no load to a 50 per cent. momentary overload occurring frequently. The speed regulation under these conditions was excellent, and standing at the exhaust pipe, the only indication of anything unusual was a puff of blue smoke. At ordinary load the exhaust was practically invisible, showing excellent conditions.

The Dominion Steel Products are to be congratulated on being the pioneers in Canada of this type of prime mover, and its development will be watched with interest by the engineering profession in general. Mr. Brown, the designer of the engine, gave a highly interesting lecture on the engine before the Canadian Association of Stationary Engineers recently, which was well attended, and discussed with interest by those present.



TYPICAL INDICATOR CARDS.

Breaking Cylinders Through Excessive Water

Some of the Causes of Damage to Cylinders Through Slugs of Water Being Drawn in by the Piston—How to Prevent Those Occurrences

OF all the causes of accidental injury to steam engines the presence of an extraordinary amount of water in the cylinders is one of the most prevalent. After the exhaust valve closes, this water, forced by the piston into the space remaining in the cylinder, has no ready means of escape. If the clearance space is quite large and the engine is running very slowly, there is a possibility of no damage resulting. If the water is sufficient to more than fill the clearance space, however, an irresistible pressure will be produced and something must give way to relieve it, says the Locomotive.

All engines are, or should be, provided with cylinder drains or drips, one at the throttle valve and one in each end of the cylinder, for the purpose of removing the water of condensation when starting. Ordinarily these drips are closed by means of a plain globe or angle valve, though in many cases the cylinder drips are fitted with spring loaded relief valves which may be opened also by hand. The principal safeguard that such spring loaded valves may afford is in the relieving of unduly high steam pressure. Contrary to a somewhat prevalent belief, valves of this type are of little or no use for draining the cylinder should water in any appreciable amount enter through either the steam or exhaust pipe while the engine is running. Water, at rest or when set in motion, has considerable inertia. When the piston drives a volume of water before it in its stroke, the water is flowing in lines parallel to the axis of the cylinder and a considerable force is required to turn it from this direction of flow. To expect it to make a sudden, right-angled turn and to converge all its lines of flow into a relatively small drain pipe is not reasonable. Even a relief in the center of the cylinder head would be wholly inadequate in a case of this kind.

Probably the most frequent result of excessive water in the engine cylinder is that the cylinder head is blown off. The head itself may be broken, the thread on the cylinder head studs may strip, or the studs or bolts themselves may pull apart, and not unfrequently the wreck may involve failure of all of these parts. Sometimes the cylinder itself may be cracked or badly broken and there are numerous instances of the excessive pressure having driven the piston on or off the piston rod. The cylinder and piston construction may be strong enough to withstand the shock and to transmit the force developed to other parts of the engine so that a piston rod may be broken or bent, a crosshead may fail, the connecting rod may be damaged, or the force may be transmitted still further to the crank and shaft of the engine so that these parts may suffer serious injury. Sometimes the shock is so great that the engine is a complete wreck. Water in an engine cylinder is, in fact, so serious a matter that every precaution should be taken to remove the possibility of its presence.

When the boiler feed water contains foreign substances in sufficient amount to cause excessive foaming and priming, there is great danger of water being carried over to the engines in amounts sufficiently large to cause damage. If the engine is some distance from the boiler and the steam pipe is exposed, there is also the possibility of excessive condensation taking place so that the engine may sometime receive a "dose" of water sufficiently large to wreck it. It is best, under any condition, to provide a separator in the steam line, which should be connected close to the engine throttle, not only for the purpose of removing excessive amounts of water, but also for the extraction of small amounts of moisture in the steam. It is always in the interest of economy to supply the engine with as dry steam as possbile.

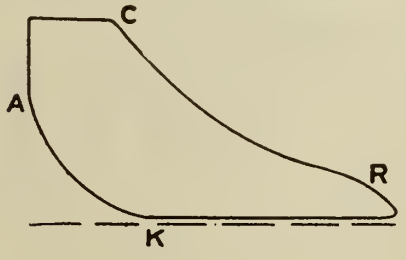


FIG. 1.

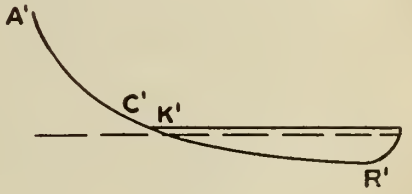

FIG. 2.

The function of the steam separator is to separate the liquid from the vapor in the steam pipe, but after this has been accomplished some means must be provided to drain the separator of the water. To do this a drain pipe is provided to conduct the water to a steam trap which will discharge the water, but not the steam, to the atmosphere. It is best to have as short and as direct a drain pipe as possible from the separator to the trap and numerous fittings and valves are to be avoided. If a valve is installed in the drain between the separator and the trap, it should be locked or sealed open. Steam traps, at times, will become inoperative from some cause and if such a condition prevails the separator, of course, is deprived of a drain so that it will accumulate water and will thereby become valueless and even dangerous. The steam trap, therefore, should be carefully watched and inspected to make sure that it is, at all times, in perfect working order.

There have been many cases of engine wreckage from water taken into the cylinder from the exhaust piping. When a cold engine is started the throttle valve is opened, of course, only a slight amount and there is the possibility of a vacuum forming by rapid condensation of the steam in the engine cylinder so that if, by chance, any water be present in the exhaust line there is great likelihood of its being drawn into the engine cylinder. Then, when the engine turns over, the water is trapped in the cylinder and is the cause of damage. To guard against the possibility of wreckage from the cause just mentioned precautions should be taken to prevent the accumulation of water in the exhaust pipe. From the standpoint of ease of removal of the water the best way would be to have the exhaust pipe so installed that it will act as its own drain, the water running by gravity to the open end of the pipe. In the great majority of cases, however, the exhaust pipe, before reaching an open end, rises above the engine cylinder so that a pocket is formed in which water may very readily accumulate. Such lines should be equipped with ample size drain pipes located at the lowest points of the exhaust pipe and the installation of these lines should be carefully studied to see that they are drains in fact and not additional pockets in the system.

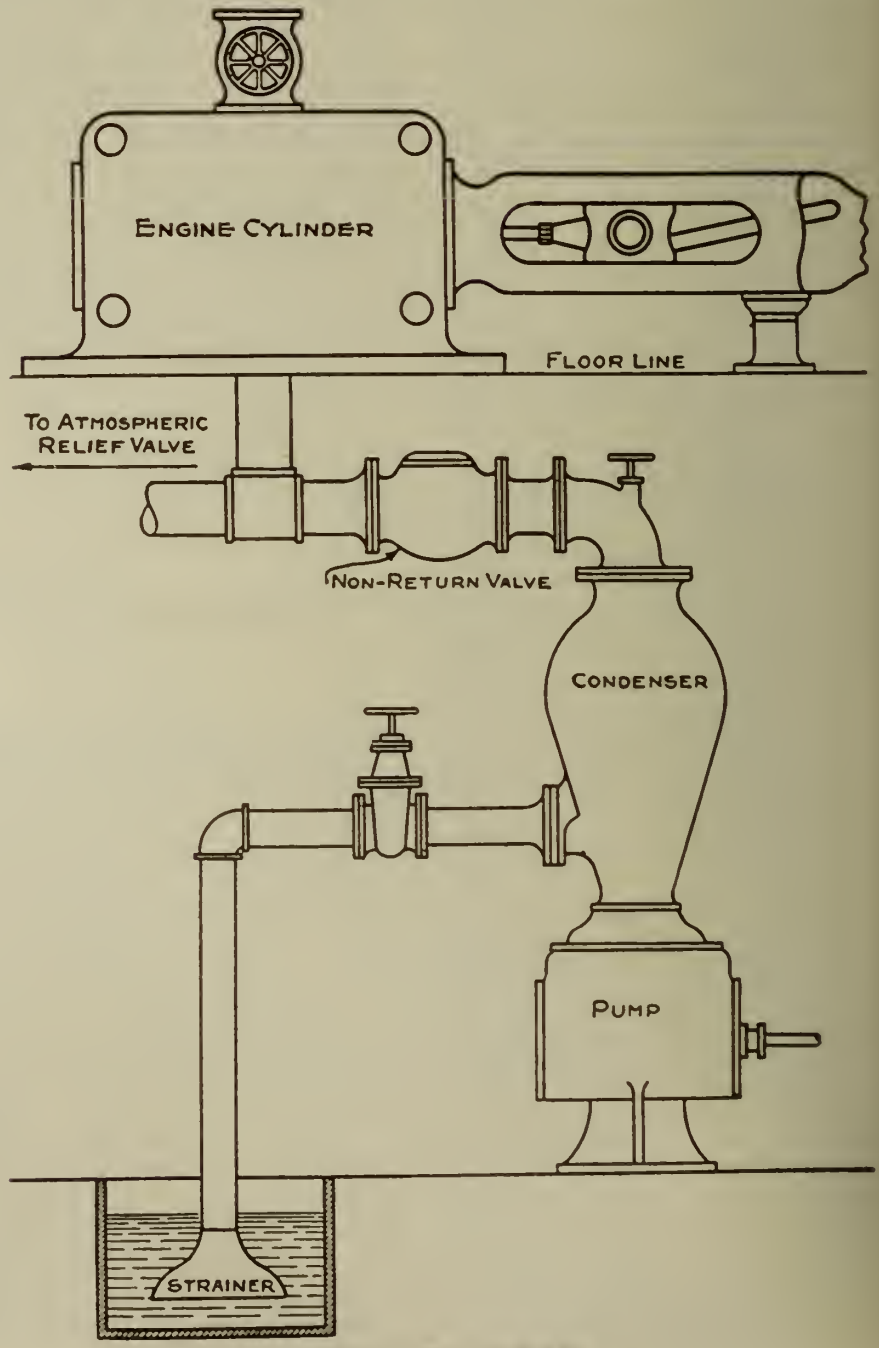
When a cold engine is to be put into operation it is necessary that certain precautions be observed before it is set in motion. If the steam be admitted to the engine too rapidly, severe expansion stresses will be set up in the engine parts which might lead to cracking of the cylinders. Furthermore, when steam is first admitted to a cold engine, and until the machine becomes warmed, rapid condensation will take place with consequent formation of a sufficient amount of water to give rise, should the engine turn over before this condensa-

tion ceases or the water is removed, to a greater or less degree of shock. It is therefore quite essential that any steam engine, before it is started, be brought up to temperature slowly and gradually. The length of time required for this is naturally a factor depending entirely on the size of the engine.

With Corliss engines, or with any other type in which the valve gear can be operated by hand, the cylinder is readily warmed by "cracking" the throttle a little and turning, alternately, the steam valves at the head and at the crank end to the open position. The valves of some engines cannot be operated independently by hand and with these it is necessary to bar the engine over from time to time during the process of warming so that both ends of the cylinder may be heated at as nearly a uniform rate as is possible. It is hardly necessary to call attention to the necessity of closing the throttle before attempting to turn the engine over. These methods of warming the engine cylinder preparatory to starting are, of course, the necessary steps for a simple engine or the high pressure cylinder of a multiple expansion engine. In the case of a compound engine it is well to warm the receiver and low pressure cylinder by means of the high pressure steam bypass to these parts, when such bypass exists, or by turning the engine over several times by hand to permit the steam from the high pressure cylinder to flow on through the engine. By thus thoroughly warming the engine before starting the danger of producing a vacuum in the engine cylinder and thereby drawing any water from the exhaust pipe into the cylinder will be greatly reduced.

When shutting down an engine there is a condition produced which makes the entrance of water into the engine cylinder from the exhaust pipe, should it be present there at such time in sufficient quantity, an almost absolute certainty. In order to understand how this condition is produced, reference will be had to some indicator diagrams. Fig. 1 shows a typical card or diagram for an average engine under load. The steam valve opens for the admission of steam at A and closes or cuts-off at C. The exhaust valve opens or releases at R and closes for compression of the steam remaining in the cylinder at K. Suppose now that the throttle of the engine is closed to stop the engine. On the next revolution, when the piston arrives at the point in its stroke indicated by K, there still will be some steam left in the cylinder and this steam will be compressed along the line K′ A′ of Fig. 2. When the piston starts in the opposite direction this steam will re-expand. At the point A′ the steam valve opens and the indicator diagram is therefore dealing with a greater volume of steam (the volume in the cylinder plus the volume in the steam chest made available by the opening of the admission valve), so that it is difficult to say just what line this re-expansion will follow. However, since the volume is increasing by the forward motion of the piston and since the steam is condensing somewhat, it is certain that the pressure will fall and it will be fairly accurate for the purpose of this discussion to say that it follows back along the line A′ K′. After the piston reaches the point in its stroke where the steam valve closes, or about at C′, the steam in the cylinder will continue to expand so that the pressure will drop considerably below atmospheric. We thus have a rather low cylinder pressure when the piston reaches the point where the exhaust valve opens. If a considerable quantity of water has accumulated in the exhaust pipe from any such cause as, for instance, the premature stopping of the pump of a jet condenser, this water may readily be drawn up with a rush into the engine cylinder. This rising of water into the cylinder in an attempt to equalize the cylinder pressure with that of the atmosphere results in the upward curve of the indicator card at the point R′.

When the engine makes the return stroke with the exhaust valve open, the water is carried ahead of the piston into the end of the cylinder. Some of it, of course, will return to the exhaust pipe, but some of it is sure to remain in the cylinder. When the water was drawn into the cylinder there were forces acting in a very positive direction to move it. After it enters the cylinder these forces are not so definite in their direction and the inevitable result will be that considerable water will be trapped in the cylinder after the exhaust-



TYPICAL JET CONDENSER.

valve closes. With the engine still turning over at close to its normal speed and with no escape for the water, the result is obvious.

With condenser operation, it is rather common practice to install an automatic device on the condenser for the purpose of "breaking" the vacuum should the condensing water rise into the exhaust pipe. These vacuum breakers consist, quite frequently, of a float inside the condenser which, when the water rises, opens a valve to admit air to the condenser above the water level so that the further influx of injection water is prevented. This principle of breaking the vacuum is entirely correct but accidents have occurred from the float becoming water logged or from sticking of the valve. If the air is not admitted in sufficient quantity to break the vacuum before the water reaches the level where the air is admitted, the danger is accentuated, for if the water passes the point of air admission the air, when it does enter, will mix with the rising column of water, which will thereby have its specific volume greatly decreased, and it will be possible for the mixture to rise to a higher level than could the liquid alone. In order to avoid the condition just mentioned, it is well to admit the air as close as possible to the engine itself and to use a vacuum breaker that is reasonably positive in its action.

A condition that is sometimes encountered and one that is extremely dangerous is that in which the injection water to the condenser is supplied under a pressure head. With this condition it is possible for the water to flow into the engine cylinder while the engine is at rest so that the machine may be wrecked upon starting up. The water should always be drawn up to the condenser by the vacuum or else the head under which it flows to the condenser should be so small that, with the vacuum removed, the water would not rise to a point dangerously near the engine.

There may be cases in which the water is supplied the condenser from a pond, the level of which at the time of observation or inspection may not be dangerous but which may at times be subject to a large fluctuation from causes such as a heavy rainfall or rising tides and an unsafe condition may thereby be produced.

A very good preventive against the entry of water from the exhaust side of the engine is some form of non-return valve which will close when the water flows toward the cylinder. Such an installation is illustrated. It is always best, of course, to have an atmospheric relief valve in the exhaust line to prevent excessive pressures building up in the low pressure cylinder of a multiple expansion engine and also, of course, to prevent immediate shut-down should the condenser equipment cease to operate. The connection for this relief valve should be between the engine and the non-return valve as indicated in the illustration.

Not only jet but also surface condensers may give trouble if the latter type is so connected that the steam enters the condenser shell at the bottom. This method of piping is sometimes used when there is no basement under the engine and the condenser is placed on a level with the engine cylinder. If the condensate pump stops accidentally, the exhaust pipe will accumulate water from the condensing steam and at the time that the engine is being shut down this water may return to the cylinder to cause damage as explained in the foregoing.

Still another source from which water may enter an engine cylinder is the receiver on a compound engine. Engines of this type are sometimes constructed with a valve gear giving a fixed cut-off to the low-pressure cylinder and are governed by a variable cut-off in the high-pressure cylinder. With a very early cut-off in the high-pressure cylinder the low-pressure cylinder acts as a pump, drawing the steam from the receiver, and this action may continue to the point where the pressure in the receiver will be lower than atmospheric. This is particularly true of an engine operating condensing. The receivers of compound engines are, of course, or at least should be, fitted with drain traps, but as these are sometimes operative only when there is a pressure in the receiver greater than atmospheric the condition outlined above will cause such a trap to cease its functioning. Inasmuch as continued operation under these conditions must result in the accumulation of condensation in the receiver, it is not long before the low pressure cylinder receives a harmful "dose" of water. Of course, the proper apparatus to use for the draining of engine receivers is a special form of trap which will operate under vacuum or pressure so that some means of removing the water is provided under all conditions.

From what has been said above it is evident that there are a number of ways and reasons for the entry of water into an engine cylinder. All of these hazards may be mitigated by the use of the proper apparatus but it must never be forgotten that such safeguards as are installed must be subjected to the most rigid inspection as to the construction and method of installation and that careful watching is needed at all times to obtain dependable service.

The Westinghouse Electric and Mfg. Co., East Pittsburg, has announced a wage adjustment, effective March 1, which cuts the present pay of workmen approximately 15 per cent. The announcement, made by H. P. Davis, vice-president in charge of operations, states that the cut is due to competitive market conditions, the decline in prices and the decrease in volume of business.

GRAPHITE AS A LUBRICANT

All criticisms of graphite can be traced directly to its impurities. The impurities in lubricating graphite my be divided into two classes: those that have a positive abrasive effect and those that act neither as abrasives nor lubricants. Artificial graphite may be made very high in carbon, but since it is a by-product of the electric furnace process of making silicon carbide, it is likely to contain traces of this, which is very objectionable, as silicon carbide is one of the most abrasive substances known. In the natural graphites the objectionable impurity most commonly found is silica, or common sand. So says Brass World, which continues as follows:

The harmfulness of the impurities depends also on the size of the particles. If the size of the abrasive particles in a graphite is greater than the average thickness of oil film, their abrasive effect will be greatest in a bearing running under uniform pressure. On the other hand, in a reciprocating bearing under high duty, where the oil film is alternately broken and restored, all the different sizes or particles of the abrasive material may come into play, and it is in the latter class of bearing that pure graphite is most essential and that abrasive impurities are most harmful.

Among the many impurities in the natural graphite we find some that are not, by nature, abrasive, but are undesirable and injurious to bearings. To illustrate, let us take the particle of a so-called flake graphite, where we have alternating layers of mica and graphite held together in a manner capable of sustaining considerable compression. Let us imagine stoking an engine at night with a layer of these laminated particles between a heavy crankshaft and a babbitt or lead bronze bearing; the inevitable result will be "pockmarking" of the bearing surfaces. The effect on a reciprocating bearing would be equally undesirable; and it will be readily seen that the jamming effect produced in a ball bearing by the use of this graphite would be ruinous.

For lubrication, the graphite should be such as to permit an infinite divisibility while in contact with bearing surfaces. It should be uniformly fine enough to practically maintain suspension in the oil or grease, so as to permit of the application of the lubricant without undue difficulty due to settling, and it should be fine enough to enter properly between the bearing surfaces without clogging; this will allow it to flow freely in the oil film between the bearing surfaces. For all ordinary lubrication with the lighter grades of machinery oil, none of the graphite particles should be coarser than 0.0003 inch; grades of graphite used with greases or heavy oils would be satisfactory if ground considerably coarser, owing to the correspondingly thicker oil film which exists with these lubricants.

Erecting and Lining Up Steam Engines

This is the Second Article Dealing With Erecting Shop Methods —Placing the Outboard Bearing and the Method of Running the Lines are Described in This Instalment

By "Fitter"

IN the introductory article on this subject we had arrived at the point where the main frame and bearing of the single cylinder engine were set up.

The next step is to set the outboard bearing in its correct relative position, and check up the machined faces of the casting, where the main bearings must be fitted in. In this operation we come to the first and real lining up in the erecting of the engine, and the method employed is practically the same as is used in the engine room.

A line is carried through the cylinder from back to front, extending through the guides and beyond the main bearing, where it is fastened securely to some convenient upright, that is either secured to the floor or is heavy enough not to be easily moved. The line is fastened at the centre of the back end of the cylinder by means of a straightedge or staff laid across the opening. At the front end of the cylinder a staff is secured, with a small hole in the centre. This is usually made by fastening a piece of tin to the staff over a fairly large opening, and marking the exact centre of the cylinder on the tin, through which a hole is made just large enough to pass the line through. At the front end of the bored-out guides a similar staff is placed, and these form guides for the centre line. Great care must be taken to get these staffs exactly central, and if there is any doubt about them it would be better to leave them out and stretch the line from end to end free of any guides.

If the line used is an ordinary builder's line there should be no difficulty in stretching it taut. Some erectors prefer to use a fine wire, which can be stretched tight by a stretching screw or small drum and ratchet gear. Having stretched the line taut, check up with callipers in the cylinder bore and guides to make sure it is central. By holding a long straightedge up against the line and placing a spirit level on the straightedge, a further check can be made.

The next step is to look up the drawing for the distance from cylinder cover to centre of crank shaft and measure this out on the line. Great care must be taken in making this measurement, and the safest way is to employ a long straightedge, such as can be found in most erecting shops, with which the measurement can be made direct. A tape measure is absolutely useless for close work, and a short straightedge, which must be moved half a dozen times in making the measurement, is far from accurate.

If there isn't any such straightedge it will be advisable to get the carpenter or patternmaker to make one. Of course, the straightedge will be marked off in feet only, but the fractions of feet are obtained by using ordinary 12-in. steel straightedge. The spot on the line can be marked for the meantime by tying a colored piece of twine round it, or a plumb bob can be dropped down and its position marked on the floor. This is one point for locating the cross line, or crankshaft centre line. The other end of the line may be located by measurement, or by squaring across from the first line. If located by measurement a straightedge of sufficient length is placed across the cylinder at the back, and the measurement taken from there in the same way as it was taken by the line. In this method care must be taken to keep the measuring straightedge square with the one across the cylinder. This can be done by dropping plumb bobs down from the cross straightedge to the floor and making a chalk line on the floor exactly corresponding to the edge of the straightedge across the cylinder. The measuring straightedge can then be squared off this by means of an ordinary square.

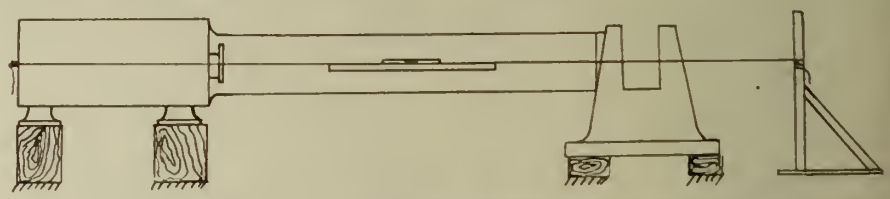
Another method is to measure from the centre of cylinder at the back the distance the straightedge is from the centre, and then measure from the line at the front end a similar distance and lay the straightedge to touch these marks. It is merely a question of parallel lines and different erectors use different means of securing accuracy.

The distance from cylinder face to crankshaft is now marked out, and the other end of the cross line located. It now remains to place uprights at each end to which the line can be secured and these should be capable of adjustment. They are placed as close as possible to the marks found, and the line is stretched across, care being taken to keep it exactly horizontal. The measurements are then checked up again, and any small adjustments that may be necessary are made.

The line can also be accurately located by means of the first line. A straightedge is laid along the first line, just touching it, and a square put against this, the blade, of course, being a guide for the line.

Whichever way the job is done it is, of course, understood that absolute accuracy must be obtained. Measurements must be checked up as the job goes along, and every precaution taken to see that nothing gets moved after being once located. These conditions having been, of course, observed, we have now the two main lines of our engine, the longitudinal axis, and the transverse axis.

The outboard bearing can now be accurately located by means of the cross line. Its centre must exactly coincide with the line and the distance from the cylinder centre line as given by the drawing can be measured off. In the case of a main bearing casting that is bolted to the girder frame it may be found that some little adjustment may be necessary. That is the bearing may be too close to the cylinder or too far away from it. If too close it simply means that a liner has to be put in between the girder and the frame where they bolt together, while if too far away the face of the girder or bearing casting must be planed to let them come together. In a shop where good manufacturing methods are in force this should not happen, but it may. A small discrepancy does not matter a great deal, as it can probably be taken up on the bearing brasses, or in the length of the rods, but it is better to stick to drawing dimensions.



LINE THROUGH CYLINDER AND GUIDES SHEWING STRAIGHTEDGE AND LEVEL.

The inboard and outboard bearing pedestals having been accurately located the lines are left in position and the main bearing and outboard bearing brasses are brought along. These will have probably been machined to fit into the casting, but not bored. They are fitted into their place on the casting and the centre line of the engine is then marked on the brass. This gives a location for the boring out of the brasses and ensures that they will be correct when the shaft is fitted in. The brasses may be bored out before being tried in a shop where they are very sure of them-

selves, but generally it is better to fit the brasses and mark them off after having placed the engine frame.

We will suppose now that the brasses have been bored out and returned to the erecting shop. The lower quarters or halves, as the case may be, are dropped into the pedestals, and the distance from the centre line to the bore of the brass checked up. This, of course, should be just half the diameter of the crankshaft. If it is less, then the brass must be made to suit, either by boring out if it has been bored too small, or if the bore is right by taking some off the outside to let it go down further in the pedestal. If the measurement shows more than half the crankshaft diameter, then the brass must be lined up from underneath to suit. We will suppose, however, that on checking up the distance is found just right. The cross line can now be taken out, and the uprights holding it moved out of the way and the crankshaft brought along by the crane. The longitudinal line will have to be taken out or dropped down while the shaft is being lowered into its place. Before lowering the shaft the journals are rubbed with red raddle, or marking, and the bearing brasses carefully cleaned. It must be noted that while we speak of bearing brasses we do not necessarily mean that they are made of brass. They will much more likely be of white metal with a cast steel shell, but it is merely the technical or shop expression. The shaft is dropped down gently into the bearings, and then, with the help of the crane, oscillated once or twice in place, and then lifted out again. The marks on the bearings are carefully noted, and if there is any fitting to be done in the way of scraping down hard lumps it is attended to right then, and the shaft lowered and raised several times till the bearing surface is correct in the opinion of the man in charge of the job. With the crank hanging down vertically, as it naturally will when left alone, the centre line is stretched again to its place, and the alignment of the crankshaft can be tested. This is done by simply bringing the crank pin up to the line first on one centre and then on the other and noting the position of the line on the pin. It is obvious that if the crankshaft is at right angles to the longitudinal centre of the engine as it should be, and the crank pin is directly central with the centre of the cylinder, the line will lay exactly in the centre of the length of the crank pin, and at right angles to it, and whatever position the crank pin is in the line should always cut the same mark. If it does not the shaft is out of line and must be corrected. However, if the erecting has been done with due care there will be no fear of that.

(To be continued)

The Transparent Rubber Co., on Danforth Ave., Toronto, will rebuild their factory which was recently destroyed by fire.

SPARK ARRESTERS

JOHN S. WATTS

The following appertains to spark arresters for the stacks of stationary or portable boilers only, not to locomotive boilers. A common fault in making these is to allow too small an area for the escape of the smoke, with a consequent choking of the draft, which may be serious enough to compel the removal of the spark arrester before steam can be raised on the boiler, with serious risk of fire until a new and larger one can be procured and installed.

In one case, where sawdust was the fuel being burnt, and the boiler was being operated in a densely wooded district, during the dry season, the risk of fire being therefore too great to permit removing the spark arrester, but with it in place no draft could be got, as it choked up almost immediately after the fires were lit. As a temporary expedient a good marksman was posted with a rifle to shoot at the spark arrester occasionally, the impact of the bullets on the arrester serving to jar the debris off the screen sufficiently to permit operating the boiler.

This method is, however, not to be recommended, the results in a populated district of a badly directed shot being likely to be disastrous to some one, to say nothing of the expense for ammunition.

The neatest and most effective shape for the spark arrester is the elliptic one shown in figure 1, and is built up on a frame made of flat bars, riveted to a band, which can be clamped to the top of the stack. This frame is covered with wire cloth, bolted to the bars of the frame.

For stacks less than 24 in. diameter the frame will be amply strong if made of three bars 2 in. by ¼ in., with a 2 in. by ⅜ in. bar for the clamp ring. For stacks 24 in. diameter and over, use four 2 in. by ⅜ in. bars, with a 2 in. by ½ in. clamp ring.

The wire cloth should have ½ in. square openings in the clear, and be made of ten gauge wire. Experience shows that a spark that will pass through a half inch opening will be extinguished before it reaches the ground. On the other hand, a smaller opening will clog up and choke the draft.

With the wind blowing against one side of the stack the smoke will be compelled to find its way out through the screen on the leeward side, and therefore one-half of the area of the spark arrester should contain an aggregate area of openings equal to the area through the stack.

In other words, the total area of the openings in the screen should be twice the area of the stack. The screen having half-inch square openings and ten gauge wires will have an area of opening equal to .25 square inches in an area of a square whose side is ½ in. plus 9-64-in., or .41 square inches. The area of the openings is therefore 25-41 of the total area.

The total area of the spark arrester therefore must be equal to the area through the stack, multiplied by 41-25 x 2, or 3.28 times the area of the stack.

The area of the surface of the screen is given by the formula,

$$\text{area} = \frac{\pi d}{2} \sqrt{\frac{4h^2 + d^2}{2}}$$

and as the area of the stack is

$$\frac{\pi d}{2} \sqrt{\frac{4h^2 + d^2}{2}} = \frac{3.28 \times \pi \times d^2}{4}$$

where d = diameter of the stack and h = height of screen. Then

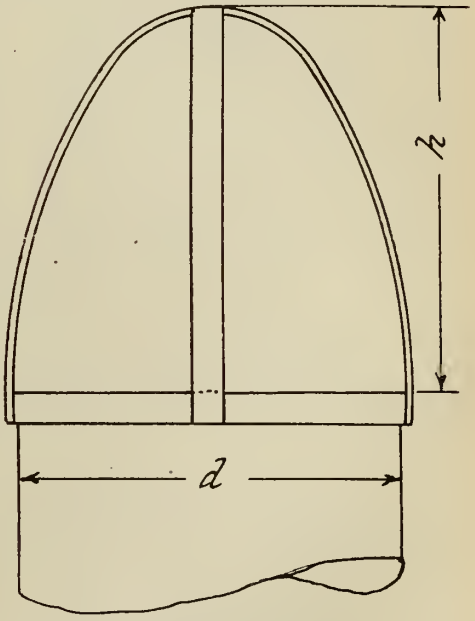
$$\sqrt{\frac{4h^2 + d^2}{2}} = \frac{1.64\ d}{}$$

$$4h^2 + d^2 = 5.3792\ d^2$$

$$h^2 = 1.0948\ d^2$$

$$h = 1.046\ d$$

Or, practically speaking, the height should be equal to the diameter of the stack.



SPARK ARRESTER.

NEW EXPERIMENTAL LABORATORY

Owing to the trend toward higher voltages which is being initiated in the West, and which will ultimately extend to all parts of the United States, the Westinghouse Company is building a complete, modern, high-voltage, experimental laboratory. In this laboratory will be installed two transformers, one rated at one million volts, 1,000 kv-a., the other rated at half a million volts, 500 kv-a. They can be connected together, and one and a half million volts can be obtained between terminals.

This will allow voltages for flashover testing as high as one and a half million volts.

The laboratory will be 120 feet long, 110 feet wide and 50 feet high, without columns of any sort. High-voltage insulators, transformer terminals and circuit breaker terminals will be tested in this plant.

Here We are Again! Perpetual Motion

From the Far Pacific Coast Comes an Inventor With a Solution to the Age-old Problem—He Says it is Perfectly Simple—See What You Think

FOR the last five years I have been trying in vain on both continents to find a man that could give more faith to scientific calculations than to our fallible science. A few days ago an action was received by me from the Patent Office, from which I quote: "Case considered as amended. It seems that there is a saving in the quantity of motive fluid used to compress a given volume of air over that required in a single cylinder. The claims stand allowable." Now this gives me great encouragement, and I ask you to be kind enough and figure out this puzzle with me and tell me how superior this air compressor is, in which there takes place air compression on entirely new lines.

Every one of us knows what an air compressor is. In figure 1 I am showing an air compressing cylinder (A) of an assumed cubic foot of air capacity at atmospheric pressure. It is connected to steam cylinder (B). If we want to compress that cubic foot of air to ten atmospheres of pressure we let steam enter behind the piston of the steam cylinder, and when the piston of the cylinder (A) reaches a certain point (e), at which point the air underneath the piston is found compresed to ten atmospheres, the valve (a) opens, the piston makes its full stroke, and that cubic foot of air is found compressed to ten atmospheres in the reservoir.

A certain amount of steam power in the cylinder (B) was required to obtain this, viz.: 144x150, or 21,600 foot-pounds. Consequently for eight cubic feet of air to be compressed to the same pressure of ten atmospheres the process has to be repeated seven more times. That is to say: 8x21,600, or 172,800 foot-pounds.

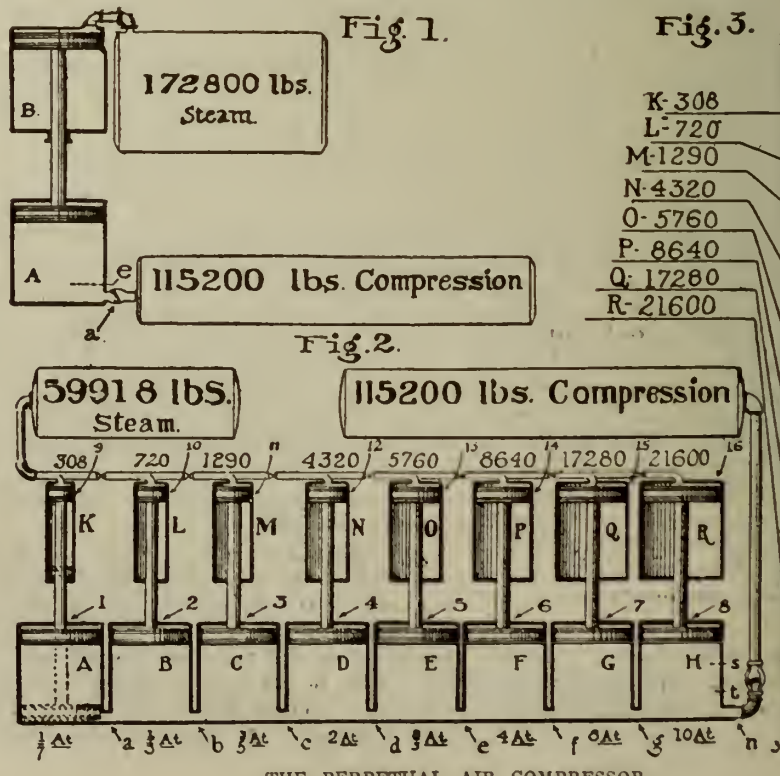
Suppose that we use back those eight cubic feet of air, compressed as we stated to ten atmospheres, viz., as a driving force in another set. We will not obtain back the whole amount of the 172,800 pounds, as some power is lost on account of friction, produced heat and other causes.

Admitting that loss in power to be approximately 30 per cent., as occurs in nearly all air compressors, we will obtain back only a force of about 115,200 pounds.

Now, let us take eight air compressing cylinders of one cubic foot capacity each (figure 2), A, B, C, D, E, F, G and H, and let us have them communicate freely to themselves by the valves or ports (a, b, c, d, e, f and g). To the piston of each of these cylinders is connected in a straight line the piston of a corresponding steam cylinder, which are, respectively, K, L, M, N, O, P, Q and R. The piston of each air compressing cylinder is found at the upper end thereof, so, in admitting air into these eight air compressing cylinders, we have eight cubic feet of air at atmospheric pressure, and running freely through the ports (a, b, c, d, e, f, g) from the first cylinder to the last. First of all, let us assume that the air compressing cylinders are jacketed by cold water, and that isothermal compression is effected, and that, step by step, compression, from left to right, is as follows:

The piston (1) of the first air cylinder makes its full stroke and it displaces or forces the air of the first cylinder to be distributed into the others through the port (a), which port (a) is closed by the piston (1), which stops at the end of its stroke (shown by dotted lines), so the air does not flow back into the first cylinder.

Let us find how much steam power (weight) was required in the first steam cylinder (K) to push the piston (1) of the air cylinder (A) for its full stroke. According to Boyle's law, that the pressure varies reversely to the volume in the compression of air, in our device, where eight cubic feet of air (volumes) are are found crowded into the seven cylinders, B, C, D, E, F, G and H, a pressure of one-seventh of an atmosphere is met. As we assumed above, that for ten atmospheres pressure, a driving force of 21,600 pounds are required, then for one atmosphere pressure a force of 2,160 pounds would be required, and for one-seventh thereof, a force of 308 pounds are required. It is therefore plain that we need only 308 pounds of pressure in order to push the piston (1) through its full stroke. The piston (2) of the second cylinder (B) is pushed down by its connected steam piston (10) of cylinder (L), and at the limit of its stroke closes port (b), so the air will not flow back. Here we have the eight volumes of air crowded into the space within the six remaining air cylinders, and in accordance with the same law we have accumulated one-third of an atmospheric pressure, which corresponds to 720 pounds of steam pressure to overcome the air pressure. At the end of cylinder (C) we have a ratio of three-fifths and consequently need 1,290 foot-pounds in the corresponding steam cylinder (M). The ratio for the cylinder (D, E, F, G) is 2, 8-3rds, 4 and 8 atmospheres, consequently we need in the steam cylinders (N, O, P, Q) these corresponding ft.-pounds, 4,320, 5,760, 8,640, 17,280. Now, underenath the last piston of the last cylinder (H), we have these eight cubic feet of air compressed to eight atmospheres. The piston is forced down and when it reaches a certain point (s), at which point the eight cubic feet of air are compressed to 10 atmospheres, the valve (n) opens and the piston continue its full stroke under a steady



THE PERPETUAL AIR COMPRESSOR.

pressure of 21,600 pounds into the steam cylinder (R).

So we have eight cubic feet of air compressed to ten atmospheres pressure by using a certain steam power, varying in each cylinder. In the first steam cylinder (K) we needed 308 pounds to drive piston (1) a full stroke; in the second, 720; in the third, 1,290; in the fourth, 4,320; in the fifth, 5,760; in the sixth, 8,640; in the seventh, 17,280, and in the last, 21,600. In all, an expenditure the total of 59,918 foot-pounds.

We clearly see, by this new device, as we have compressed eight cubic feet of air to ten atmospheres of pressure by using only 59,918 foot-pounds pressure in the steam cylinder, while if the compression takes place in a single cylinder, then the same amount of air to be compresed to the same pressure, we need 172,800 foot-pounds, effecting a saving by my device of driving force of 112,882 foot-pounds. That means about 300 per cent. efficiency, or, allowing 30 per cent. loss from friction, an efficiency of 210 per cent. The more cylinders employed, the better the result. Many scientists I have consulted, and no one has been able to prove these calculations faulty, but because they lead to over 100 per cent. efficiency, they all draw back and say that science does not admit anything like that.

I possess two letters from two professors. One replied that the fault lies in my believing that I can use different driving force for each one of the cylinders, while the other said that with one cylinder the same results can be obtained. Now, who is right—these professors or the examiners in the Patent Office who sent me the aforesaid action? Can there be a controversy in such matters?

Now, suppose that we want to compress eight cubic feet of air to twenty atmospheres pressure instead of ten atmospheres. Let us see what expenditure of force is required. Do we get the same efficiency, or more? We assumed that to compress one cubic foot of air to one atmosphere by a single cylinder (figure 1) we need 2,160 pounds. To compress it to twenty atmospheres we need 2,160x 20, or 43,200 pounds. For eight cubic feet to be compressed to twenty atmospheres of pressure we need 43,200x8, or 345,600 pounds.

Now, in our device (figure 2), to compress those eight cubic feet of air to twenty atmospheres, only in the last cylinder, we exert 43,200 pounds of pressure, instead of 21,600, which was required for the ten atmospheres. The other ratios for the other cylinders will remain the same as formerly, where ten atmospheres of pressure was required—viz., we have 308 plus 720 plus 1,290 plus 4,320 plus 5,760 plus 8,640 plus 17,280 plus 43,200, which will equal 81,518 pounds of force.

Now, the 345,600 pounds of force required in the single cylinder compression minus the 81,518 pounds of force employed in my device, will leave 264,082 pounds of force saved, or about 400 per cent. efficiency.

But one may ask, "What really takes place here that only you clearly can see?" It is the simplest thing on earth. It needs only a little devination. Let us take, for example, the cubic foot of air of the first cylinder (A). To displace it from the first cylinder we need only 308 pounds of steam pressure in the first steam cylinder (K). This cubic foot of air is compressed in the last cylinder (H) to ten atmospheres pressure without any further expense, viz., if we use back that cubic foot of air being compressed to ten atmospheres, allowing a loss of 30 per cent, there will be left to us 21,600, less 7,200 pounds, or 14,400 pounds, but we actually employed only 308 pounds of driving steam pressure in the first cylinder, so we obtain an enormous efficiency of 4,800 per cent. You see, in the last cylinder all the eight cubic feet of air are compressed to ten atmospheres of pressure by a steam pressure of 21,600 pounds. Now, supposing that we had only one cubic foot of air in the last cylinder, as it happens in figure 1, then, in compressing it to ten atmosphere pressure again, the same steam pressure of 21,600 pounds would be required. You may see, in our device the valve (n) opens when the piston is found at the point (s), while in the single cylinder compression it opens farther down at point (t). So, you see, instead of one, we have eight cubic feet of air compressed to ten atmospheres, while actually we use in both cases the same driving steam pressure of 21,600 pounds.

Again, to displace the air of the second cylinder, we need 720 pounds, and when this is found under the piston of the last cylinder and compressed to ten atmospheres, an efficiency of 2,000 per cent. is attained, and so on down to the last cylinder, where things are reversed and a loss of 30 per cent. has to be admitted, but which loss is overbalanced by the tremendous and more than 100 per cent. efficiencies that we obtain in the first stages of the compression, where the resistance of the air is small and where small pressures are required. I cannot make it any plainer.

Many have told me that by using a long single air compressor of equal diameter to one of my multiple cylinders and equivalent in capacity to the eight of them, that the same results are attained. Now, to this we say that the steam at ten atmospheres pressure is distributed at even density from one end of a long steam cylinder to the other, while in our device, by employing the cylinders (K, L, M, N, O, P, Q, R), we can regulate the steam and employ different driving steam pressure in each cylinder, according to the resistance met in the air compressing cylinders. Do not confuse this device with the stage compression. In a stage compression the air compressing cylinders are not connected freely between themselves. This law that the pressures vary reversely to the volumes cannot apply in stage compression.

In figure 3 I am showing the steam cylinder of an air compressor eight times the length of the cylinder of figure 1. There every one can see that the space (y) of steam cylinder 1, 2, 3, 4 will denote the saving in driving steam. Now, cannot any one of you determine to how much that saving comes, or how far my calculations are correct?—H. Nicholaides, 560 Fifth St., San Diego, Cal.

Editor's Note.—We should be glad to see some comment from our readers on this discovery.

TRADE ANNOUNCEMENT

The Conveyors Corporation of America, formerly the American Steam Conveyor Corporation, Chicago and New York, announce that S. D. Inman has been placed in charge of the engineering and design of their American Trolley Carrier, monorail conveying equipment for handling coal, ashes, sand, gravel, and like bulky materials from railway car to pile, bin or bunker. Mr. Inman is a conveyor engineer of considerable experience and ability, and has been associated with the Conveyors Corporation in an engineering capacity for over a year.

CATALOGUES

We have received Bulletin 19 of the Direct Separator Company, Syracuse, N.Y., describing the steam and oil separators made by that firm. These separators are made in two styles, vertical and horizontal, to suit the particular circumstances of the installation. There are also horizontal and vertical oil separators for low pressure lines and low pressure steam turbines. The catalogue is full of information with diagrams showing installation space required, shipping weight, etc. The Direct Flanged Steam Fittings are described in another catalogue issued by the same company.

The Progress Products Company, Philadelphia, have issued a folder describing their Producto Combustion Guide. This device is a combination of steam flow meter and multiple differential draft gauge. It is claimed that it is easy to read, rugged in construction, readily adjustable, and entirely new in principle.

The Holden Company, of 354 James St., Montreal, are distributing to the trade a very attractive calendar of the Chicago Pneumatic Tool Company. The calendar is printed on coated stock, 12 inches wide by 24 inches deep, the upper section of each page carrying a large reproduction of one of the applications of one of the company's air-operated tools. The entire calendar is neatly arranged and well deserving of a place in any engineering office.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

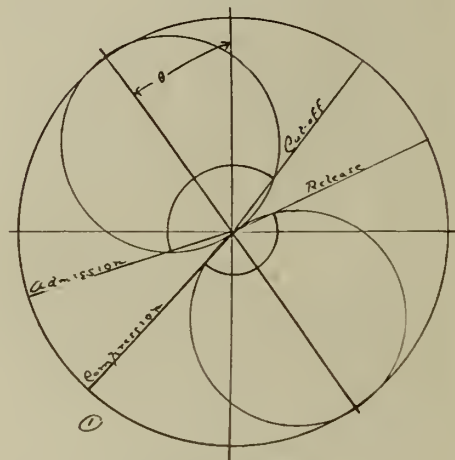
IT will be noticed in diagram shown in our last issue that the events on only one side of piston were shown. The events on the other side could be shown in just the same way, on the same diagram, or on a separate one. In showing the events on the same diagram the outside lap circle for the crank end would be laid off on the lower valve circle, and the inside lap on the upper. If cut-off was to take place on the return stroke at the same point as on the outward stroke, correction of the outside lap would have to be made accordingly. This would be done by laying off the necessary position of crank to correspond to position of piston at required cut-off, according to the length of rod. Then the point at which the crank cuts the valve circle would be the radius for the lap circle. This is illustrated on the accompanying diagrams.

Effect of Altering Laps

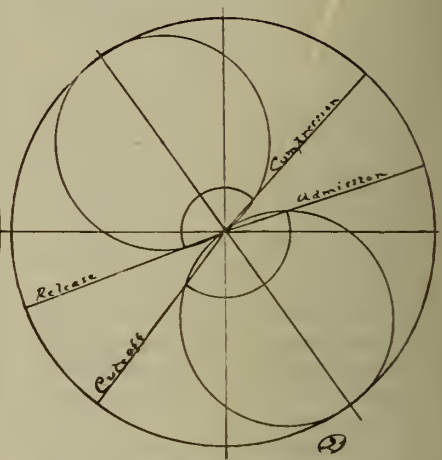
Supposing that we increase the outside lap. The events at that end of the cylinder, the eccentricity, remaining the same, would be altered in the following manner. Lead would be later, and cut-off earlier, as can be plainly seen from the diagram as compared to the original. Increased inside lap will make release late and compression early. Conversely, decreased lap outside will make admission early and cut-off late, while decreased inside lap will make release early and compression late. These effects can be seen quite plainly on the diagrams.

Altering Advance of Eccentric

Now, if instead of decreasing or increasing the laps on the valve itself we were to move the eccentric either further away or closer to the crank we would immediately have effected a change in every function of our valve, at both ends of the cylinder. If the eccentric were moved ahead, or, say, further in advance of the crank, we should have every event occurring earlier in the stroke. A moment's thought will show that this must be so. Increasing the angle of advance means that with the crank on the dead centre, the eccentric is closer to its extreme outward position. This means that a very short travel of the crank brings the eccentric past its extreme point, and the valve moves in towards its cut-off position so much earlier. Steam is cut off sooner, and the eccentric, still traveling towards its other extreme position, opens the valve to exhaust at a correspondingly earlier position. It reaches its extreme position and starts to return,



HEAD END DIAGRAM.



CRANK END DIAGRAM.

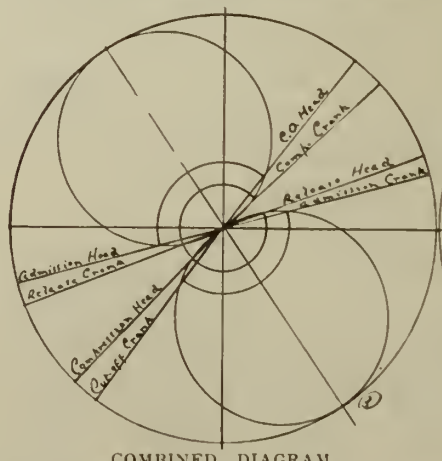
closing the exhaust while the crank is still comparatively a long distance from the end of its stroke. Thus, we have early lead, early cut-off, early release, and early compression.

Moving the eccentric back towards the crank or decreasing the angle of advance has exactly the opposite effect to that just noted. We would get late lead, cut-off, release and compression.

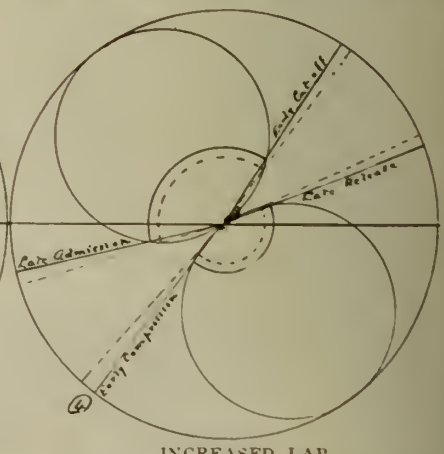
Increasing Eccentricity

If we increase the eccentricity, we shall, of course, increase the travel of our valve. The lead will be greater, that is, admission earlier. The cut-off will be later, release will be earlier and compression later. In other words, we shall have greater port openings.

By comparing these different diagrams



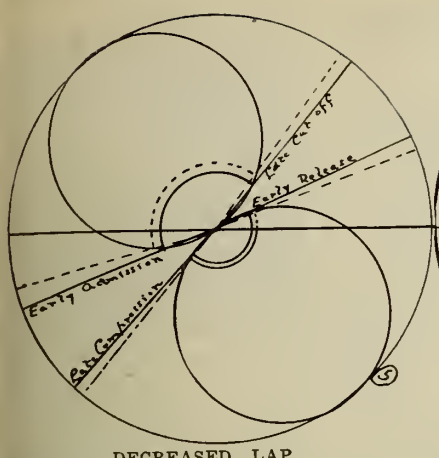
COMBINED DIAGRAM.



INCREASED LAP.

the various effects can be plainly seen. Supposing now that we have a valve that has become misplaced on the spindle. We will suppose that owing to wear the gear has all moved closer to the eccentric, bringing the valve with it. Now the travel remains the same, the angular advance remains the same, and the only thing altered is the position of the valve relative to the crank. The effect is precisely the same as decreasing the outside lap at the top, and increasing the outside lap at the bottom. The inside lap at the top will be practically increased, and at the bottom decreased. We shall have at the top early lead, late cut-off, late release, and early compression. At the bottom will be late admission, early cut-off, early release and late compression.

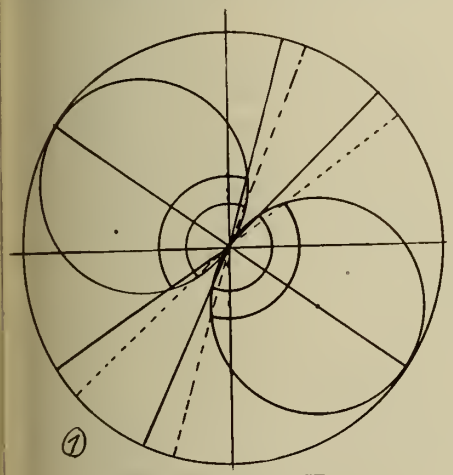
There are other valve diagrams, but they are all on much the same principle as the Zeuner, and it is easy to follow any others if the Zeuner is well understood. Careful study of the diagrams here reproduced will make it quite clear to all how the steam distribution is affected by alteration of any part of the valve or eccentric. These effects are clearly shown on the indicator cards, and thus we have two very important aids to our study of the valve. The diagram



DECREASED LAP. LAP CORRECTED FOR CONNECTING ROD.

shows us clearly and with but little effort just what will occur to the steam distribution under any given circumstances. It then becomes an easy matter to arrange our valve and eccentric to give the results shown on the diagram.

The indicator card, on the other hand, is a diagram of what the valve is actually doing at the time the card is taken. The various events are clearly shown, and it is then easy to see just how much the performance of our valve is varying from what it was designed for. The necessary measures to correct the faults are also clearly indicated. In order to illustrate this clearly in our next article



ECCENTRIC ADVANCED.

we will take an indicator card, drawn from a Zeuner diagram, and then show the effect of the various changes on the indicator card.

SECURING PROPER LUBRICATION

Sluggish action of oil-rings leading to improper lubrication of motor bearings was cured by bevelling the sides of the rings of motors made in a large New Jersey factory after considerable searching for the reason for the trouble. On testing these motors, says Electrical World, it was noticed that the ring would creep along at a very slow speed, two or three revolutions a minute on a machine of several horse-power, instead of the regular speed of about thirty to fifty revolutions. Though all journals and rings were made in large numbers and as nearly alike as possible, this trouble appeared on only about one machine out of ten, and disappeared nearly every time a new ring of the same size and shape was put in. Sometimes, of course, it was due to the ring rubbing against some projection on the casting, but more often no apparent cause was found by the assembling department. At that time the oil-rings were cut from a rather heavy brass tube with straight sides, making the cross-section rectangular in shape, while the journals had a straight slot about twenty to twenty-five mils wider than the ring.

It was finally discovered that under certain conditions the ring would start with the machine and perhaps come up to normal speed, but soon work itself towards one side of the slot and slow down, hugging closer and closer until there was only a very thin film of oil between the ring and the flat part of the journal.

Therefore, in an attempt to prevent sticking, three rings were removed and their sides were slightly bevelled, when the trouble entirely disappeared. Since that time all oil-rings are bevelled either from the outside or from the inside, and there has been no sticking.

POWER FROM WASTE WOOD

The progress which has been made by British firms in the construction of suction gas plants for utilizing waste wood should be of special interest to this country, where there are still large quantities of wood available. These plants distil the wood and produce gas which is of excellent quality for use in gas engines. This method of utilization is said to be more economical for power producing purposes than burning under a boiler. A recent example of a large installation on these lines is afforded by a mine in a British Dominion, where four suction gas plants capable of yielding a total output of fourteen hundred horse-power have been installed. The fuel used is in the form of logs up to two feet long and a foot in diameter; and the gas is applied to the driving of four horizontal gas engines. Three of the engines drive electric generators and the fourth is coupled to an air compressor for operating pneumatic drills and hammers in the mine.

GOING AHEAD TO LOCATE COAL

Reports of provincial analysts and other kinds of geologists have not cooled the ardor of those who believe there is coal around Shelburne, Dufferin County.

A while ago investigations were made, and as a result a very discouraging report was made to the effect that the chances of finding coal in such surroundings were nothing at all.

The sequel comes in this announcement in the Official Gazette:

Two million dollars is the authorized capital of the Chamberlain Coal and Oil Development Co., Ltd., which has been granted letters patent and will have its head office in the village of Shelburne.

The new company under its charter is authorized (a) To acquire, own, lease, prospect for, open, explore, develop, work, improve, maintain and manage mines and mineral lands and deposits; and (b) to take, acquire and hold as consideration for ores, metals or minerals, including oil and gas, sold or otherwise disposed of, shares, debentures or other securities and to sell and otherwise dispose of the same; with a capital of two million dollars, divided into two million shares of one dollar each; its head office at the village of Shelburne, in the county of Dufferin.

The Combustion Engineering Corporation, New York, have issued a most attractive calendar, which is a beautiful specimen of color printing. The various months are headed by a colored engraving depicting various types of stokers, and also a pulverized coal installation. The types of stokers include the type E, the Coxe, Lopulco Pulverized Fuel System and the type H, all products of the Combustion Engineering Corporation.

Canada Keeping Up

THE opening article in this issue of Power House is a description of a Canadian made Diesel engine. This is not the first description of a Diesel engine that has appeared in the pages of Power House, but it is the first time that a Canadian made Diesel has been described for the very good reason that it is the first engine of this kind built in our Dominion.

This engine is running daily, and is a successful commercial article. Other firms in Canada are developing other types of internal combusion engines, so that we are not likely to be behind the rest of the world in this particular development. There are a large number of places in Canada where the Diesel engine or its near relation, the hot bulb engine, can find a very useful sphere. With the discovery of what appears at first glance to be the largest oil field in the world at Fort Norman in North-Western Canada, the development of the country will be hastened in every direction.

It is time for the power plant engineer to familiarize himself with these engines as far as he possibly can, so that he can step into the breech when needed.

Protecting the Fireman

IN a recent issue of a journal which specializes in technical subjects arranged for the understanding of the layman, there appeared recently an article of interest to the engineering profession.

From this it appeared that the man who is engaged in the task of generating steam in the boiler by shovelling coal is frequently inconvenienced by the heat. This is somethin we have noticed ourselves, but it is nice to have it confirme by such an authority. We must confess, however, that th way to avoid this inconvenience had not previously suggeste itself to us. This is all the more remarkable as it appear so simple. All that is required is to make the furnace door and fronts hollow, and through the passage thus forme circulate cool and refreshing water. The author goes furthe and says this system can be applied to other parts of th boiler. Why of course it can! When we come to think of i there are lots of places it could be applied. For instance imagine what a delightful place the boiler room would be come were the shells of the boilers jacketed before the lagg ing was put on. The steam pipes could be run through larger pipe, with circulating water in the space betweer There would be all kinds of comfort in the boiler and engin room then.

However, we always had the idea that all the heat possible should be retained in the boiler and steam pipes. Th method of keeping boiler furnace doors cool always seeme to us to be by keeping the fire clear of the dead plate, as w always found that burning coal on the dead plate didn' help the generation of steam greatly. On the other hanc it was good for the manufacturer of arch bricks, furnac door baffle plates, etc.

Again we must confess, however, that the simple ide of a water jacket never entered our head.

It Crops Up Again

SOMETIMES we think the type of inventor who believes h can get more out of a machine than he puts in has die out. Then suddenly our hopes are shattered, and from ou of the void comes a voice crying "Eureka! I have found it." Needless to say the owner of the voice only thinks he ha found it. It isn't there to find.

In another part of this issue we print an account by one N Nicolaides, of a machine, or principle, by which he claims h can do roughly 173,000 foot-pounds of work in an air cylin der by the expenditure of 60,000 foot-pounds in the steam cylinder. The method he proposes is somewhat involved, an requires careful reading before his idea is grasped. How ever, we still believe that Baylis Law holds good, our inven tor to the contrary notwithstanding. He traces back the pro phecy of his invention through the shades of Greek myth ology, leading up to a vision which was vouchsafed to him which started him to thinking deeply. The outcome of hi thoughts is the fearful and wonderful discovery described o another page.

This inventor is generous. He wants no reward but re nounces his claims freely to the government and the people He wishes the government to proceed gradually with th manufacture, as he does not wish existing industry to b shattered at one fell swoop. He is quite ready to appea before a body of scientists and engineers, and if he does no convince them, will voluntarily retire to an asylum. Tha would seem to us to be a wise step.

The machine has never yet been built by man which is 100 per cent. efficient, let alone over 100 per cent. We doub very much that it ever will. The fundamental principle tha you cannot get more out of a machine than you put in re mains as immutable as ever. If ever that condition shoul be changed, then indeed would this world, in the words o Mr. Nicolaides: "Be transformed from a vale of tears to a veritable Paradise."

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

ZEUNER DIAGRAMS AND CALORIMETERS

Question.—Would you kindly explain the Zeuner diagram and also the principle of the steam calorimeter?

Answer—The Zeuner diagram has been explained in the last issue and also in this issue in the Course of Instruction. Calorimeters are of two kinds, the throttling and separating types. In the throttling calorimeter steam enters an upper chamber and passes to a lower chamber through a diaphragm. In the top chamber a thermometer is placed, and also in the lower chamber. The passage of the steam from the top chamber to the lower one through the diaphragm is restricted by the small orifice in the diaphragm, while the outlet from the lower chamber is large, and to the atmosphere. Therefore, the steam coming from the top chamber is wire drawn, and superheated by reason of it expanding without doing work. The reading on the lower thermometer will give the amount of this superheat, and if there is moisture present in the steam the superheat will be less, on account of part of the heat of the steam having gone to evaporate the moisture. The following formula will give the degree of moisture in the steam.

Let.

T=Temper. of steam on high press. side;
t =Temper. of steam on low press. side;
H=Total heat of steam in upper chamber (H.P. side);
L=Latent heat of steam in upper chamber (H.P side);
q =Heat of liquid in upper chamber (H.P. side);
C=Specific heat of superheated steam at exhaust pressure;
x=Initial quality of steam;
1—100x=initial moisture in steam p.c.

The total heat of a pound of wet steam flowing into the orifice is $xL+q$ and after expansion assuming that all the moisture has been evaporated the total heat of the same weight of steam will be $H + C\ (T—t)$.

Then if no heat has been lost these two quantities should balance each other and we get the equation

$$xL + q = H + C\ (T — t)$$
$$\text{and } x = H + C\ (T — t) — q.$$

The orifice is from 1-16 to 3-32 diameter, and the weight of steam discharged per hour can be found from Napier's formula $\frac{PA}{70}$ equals the pounds per second where P is gross pressure and A is area of orifice. The use of this type is restricted to cases where the steam only contains a small percentage of moisture, say up to 5 per cent.

For cases where the moisture content is higher a separating calorimeter is used. In this instrument the moisture is separated from the steam by a process similar to that taking place in an ordinary steam separator. The total amount of steam flowing can be found from the area of the orifice by Napier's rule, and the ratio of the moisture to the total amount is, of course, the moisture content. A pressure gauge with two scales is attached to the instrument, and this shows pounds of steam per minute according to pressure. A scale is sometimes supplied which reads on the gauge glass the amount of moisture in pounds per minute passing through. If this is not on the instrument, the condensation discharged from the instrument can be weighed and corrected against the average weight of steam over a certain period.

BOILER RATING

Question—Would you kindly answer the following question through Power House. A third-class stationary engineer's license allows the operator to run a plant up to 300 h.p. Now suppose we take a 300 h.p. boiler and increase its rating to 200 per cent. Will the new license law still allow a third-class licensee to operate the boiler?

Answer—The rating of a plant for the purposes of the license law is based on the heating surface corresponding to a boiler horsepower according to the style of boiler. Thus, a H.R.T. boiler is rated at 15 square feet to a horsepower, a water tube boiler at 10 sq. feet and so on. Now it is quite obvious that no matter how much the rating of the boiler may be increased owing to increased combustion, the heating surface will remain the same. The evaporation per square foot of heating surface increases, but that does not affect the rating of the boiler so far as the license law is concerned. If it were possible to force the boiler to 1,000 per cent. rating it would still be a 300 h.p. boiler as interpreted by the law.

AN ELECTRIC GENERATOR QUERY

Question—We have a 30 K.W. alternating generator and a 2 H.P. D.C. generator. The reading on the name plate of the D.C. machine is R.P.M. 1625 plus or minus 5 per cent., 2 H.P., 15.6 amps. When the load is as high as 22 amps. it is hard to raise the voltage only by turning the rheostat over a number of sections, may be as many as six, before the voltmeter shows an increase. With 10 amperes it works fine. There has always been a wave in the machine light, which made me think the D.C. machine was running too slow, so I speeded it up a little and made some difference. Would like to know what the plus or minus 5 per cent. means. Does it mean to increase the speed of the machine after the 15.6 ampere mark is reached, and is it a good thing to increase the speed of the machine?

Answer—With a load of 22 amps. you have a considerable overload on the machine, and it will necessarily make it hard to raise the voltage. Increased speed gives increased voltage by increasing the field strength. The marks on your machine may mean that the generator is designed to work within those limits of speed over or under the normal, or it may refer to the over or under compounding of the field winding. It would simplify matters if you were to give more information about the D.C. machine, its style of field winding, and the purpose it is used for. Also just what do you refer to when you say there was a wave in the machine light? Remember, when you write in a question like this that we have not got the installation in front of us like you have, and therefore we need all the information you can give in order to give an intelligent reply.

LIFT OF PUMP VALVES

Question—Would you kindly advise in your next issue what lift pump valves should have according to size. If not properly adjusted would it affect the stroke of the pump?

Answer—Pump valves are usually arranged to have not more than about 3-16 to 1-4 inch lift on large sizes, and from 1-8 to 3-16ths on small sizes. The valves are made of sufficient diameter to equal the area of the cylinder with this amount of lift. Generally speaking, the smaller the lift the easier it will be on the valves, and the longer they will last. The de-

livery valves are sometimes made with a little less lift than the suction in order to obtain a higher velocity of discharge. The effect on the stroke of a pump would not be noticeable unless the suction valves, for instance, had too little lift. Then the pump cylinder would not be filled on the suction stroke and a jerking action would result. If the delivery valves have too little lift, the pressure will be raised in the pump chamber and the pump would slow down. In some pumps the valves are made very small and a large number of them put in, and the lift made smaller than usual.

CHAIN SLINGS AT AN ANGLE

Question—Could you give me a formula for the stress in the links of a chain when lifting at an acute angle, as for instance, in lifting a cylinder cover with two chains attached to one central hook, or with one chain with the hook in the middle?

Answer—This is a question that sometimes comes up, and is somewhat difficult to answer. At first glance, one would say that a chain being a flexible body, is under no strain except that due to a direct tension, whichever position it may be in. The case of the lift being made by two separate slings, or practically two legs, approximates closely to a chain having a direct tension. If the chain is fastened across the top of the lift and caught by the lifting hook in the middle, then the case is different. The link which is caught by the hook is subject to a bending moment and also a compressive stress, instead of the direct tensile stress which it is usually subjected to. It is difficult to make a hard and fast rule, but would say that when a chain is to be used in the manner last indicated, an ample margin of safety should be taken. With a chain lifting at a slight angle as in the first case, the load should be assumed to be two-thirds the total load in each leg, instead of one-half, with two chains. If any of our readers have made a mathematical investigation of this subject, we should be glad to hear from them.

C.A.S.E. ACTIVITIES

An interesting evening was spent at the Toronto Lodge of the Canadian Association of Stationary Engineers, on Wednesday, the 23rd February. The occasion was an open meeting, and a goodly number of the members and visitors turned out to hear a lecture on the Diesel engine delivered by Mr. W. Brown, of the Dominion Steel Products Co., of Brantford.

Mr. Brown, who is the designer of the engine built by his firm, and which is described in another part of this issue, gave a very lucid description of the Diesel engine in general, and the particular engine designed by him. He handled the subject in an entertaining manner, and all those present were able to fuly grasp the principles elucidated.

The executive officers of the lodge are to be congratulated on their initiative in securing such an interesting event for their open meeting.

We understand that the lodge will be holding a banquet during this month, particulars of which will be given later.

NATURAL GAS AS FUEL

By Elmer S. Hodges

There exists in the West with Medicine Hat as a centre an immense field of natural gas which is obtained from wells averaging 1,000 feet in depth, at a pressure of about 500 pounds per square inch, with a volume of 2,500,000 cubic feet per twenty-four hours. This is a fair average of fifteen wells. The constituents of the gas are CH_4 99.49 per cent., H_2O .51 per cent., or about 89 per cent. methane and 10 per cent. carbons. Tests show 1,150 B.T.U. per cubic foot, against 57 per cent. methane and 600 B.T.U. for coal gas. A very much greater quantity of air is required for combustion owing to the very high percentage of methane, consequently a smaller quantity of gas is used per unit of work done.

The gas has little or no odor and when combustion is properly carried out leaves no residue on boiler or brickwork. A reducing valve is installed at the well, and the gas enters the mains at a pressure of ten ounces and is delivered to power plants at about 6 to 8 ounces. The burners in use vary from a piece of iron pipe with holes punched in it to the highly finished adjustable burner. In the furnace a chequer brick wall is built close to the discharge point, and this becomes red hot when it acts as a refractory and ignition wall. To change from coal to gas requires but little adjustment. All that is needed is a layer of brick on the bars, or closed ashpit doors, so that all the air for combustion must pass through the burner. Practically all types of boilers are operating with this fuel. It is usual when boilers have to be banked up to leave a small pilot burner which supplies enough heat to keep steam up near the working pressure. There are also regulating valves which adjust the burner to changes of load, and will keep the steam pressure up to within a variation of 3 per cent. up or down.

The writer has noticed cases where coal fired boilers after being changed over to gas have developed bagged tubes and plates, and has been somewhat at a loss to account for it. After the defects have been repaired no further trouble has been experienced. The writer has formulated a theory for this notwithstanding the opinion of leading engineers that the cause is nothing more than dirty heating surfaces. He would welcome other opinions.

The gas is also used in steel mills for heating ingots, in glass works for heating retorts ,and also of course for gas engines. Heating and lighting are two of its most important uses. The cost of the gas is 5 cents per thousand cubic feet for industrial users, and 15 cents less 10 per cent. to domestic users.

Round houses find the gas most useful, as, besides supplying the fuel for the power boilers, it is piped round the house and used for tire shrinking, heating frames previous to straightening, melting babbitt right at the job, and so on. It is used also for raising steam on boilers when they are ready to go out. When this was first tried, the correct position for the burners was not realized. They were first placed under the grates, with the result that several grates were burned out. The next position tried was under the coal on top of the grates, the result being the burning out of the burners themselves. The final position was on top of the coal, which is laid on the grate ready for lighting up. Natural gas is also used for lighting Pullman cars, as it mixes quite well with the Pintsch gas and gives good results.

The gas field has been exploited for about fifteen years without any sign of exhaustion.

HOLDING A PULLEY

By J. Ellethorn

When a split wood pulley slips on a shaft and tightening up on the bolts fails to hold it, a piece of sandpaper or emery cloth is placed around the shaft, with the grit side next the shaft, the pulley being placed over it.

There can be no doubt that some writers advising the use of this plan have succeeded in making a satisfactory job, for temporary use at least.

In case the pulley is in a location where oil or greasy vapor can come in contact with it, the grit on the paper will become separated from its base when the oil works in, and a slipping pulley will result. I have seen two cases of this description where the pulley slipped for a considerable time, and the grinding effect on the shaft was so bad that the pulley had to be moved to a different part of the shaft. When the bushing in a split pulley becomes oil soaked, so that it will slip even when quartered, I would advise the use of coarse fibre wrapping paper instead of sandpaper. Then, if there is a slip, no damage will be done to the shaft.

CIRCULAR SLIDE RULE

In order to assist engineers to calculate the size of pulleys and width of belts for transmission problems, a British firm has developed a circular slide rule by which all the details required can be ascertained with rapidity and accuracy.

The death occurred on February 26 of G. R. Baker, 615 Huron St., Toronto, who for many years had been a member of the engineering firm of Westman and Baker. He was an active member of the Lakes Association of Muskoka, and commodore of the Toronto Canoe Club.

Regulating Overflow in Hydro Power Plants

Various Methods Used in Modern Hydro-Electric Stations are Described in This Article, Together With Some Features of Their Operation.

By F. A. SWEET

ARRANGEMENTS for wasting excess water are provided by the use of Taintor gates, sluice gates, bear trap gates, automatic rolling gates, automatic flash boards and gate or flutter valves located near the bottom of a dam.

Wide spillways without gates are also used to waste excess water. When flash boards are installed their purpose is rather to increase the effective head and storage of the river than to waste water. This also may be said of needle stop logs, excepting where they are used instead of gates at the older dams.

Taintor gates are now one of the most widely used gates. They can be raised or lowered easily, as the pressure of the water is taken care of with bearings.

Either hand, motor or interchangeable hand and motor driven hoists are used to operate them. When each gate is not provided with an individual hoist a track is laid on top of the dam to carry a portable hoist. Care should be taken with this type of gate to prevent logs or large cakes of ice jamming them, and that the lifting chains pull equally, otherwise the gate may be wrenched out of shape, which will interfere with their successful operation. Turn-buckles are used on these chains for adjustment. Stop log grooves are usually provided in the dam structure to facilitate work which would require that the water be shut off from the gate. It is difficult to fit stop logs so that no leaks appear, but these can be stopped with cinders.

A wide variety of sluice gates are in use. When these gates are provided at the crest of the dam they are often lowered to waste water. They are therefore very convenient for sluicing ice, logs and other river trash.

It is usual to find booms which bypass this trash into racks. When these gates are built primarily for discharging trash they are sometimes built rather small, so that a minimum of water is used in discharging the trash.

Rack and pinion operated gates are in common use. One or two rack stems are bolted to the gates and the pinion can be back geared for motor, manual or interchangeable operation.

If the gates are designed for hand operation, either hand wheels, cranks or levers are supplied. Some sluice gate hoists have arrangements provided to shift gears so that the operator can select the gear ratio best suited to the conditions. Where a worm or gear is used in the hoist it is convenient because it holds the gate in any position without the use of a brake or stopdog. These gates can be built bearing on rollers so that there is much less friction.

Sluice gates located near the bottom of a dam are very convenient for wasting water in a freezing climate, as the operating stem is the only part which freezes fast and this is not hard to chop free.

These gates waste a large amount of water for their size. For example, a four by four gate at a depth of 29 feet discharges 430 cubic feet per second. This type of gate has been used to render a double service at plants where the tail water rises high enough to curtail the station output during floods. The gates are located so that the water discharging into the draft tube results in an increase of power output of the turbines.

Some sluice gates are provided with adjusting wedges to take up the water if the gate becomes leaky after long usage. These submerged sluice gates are very similar to large gate valves which are also used for similar purposes, so it may be well to consider them at the same time.

Both rising and non-rising spindles are also used to operate these gates in which case remote control by means of valves can be resorted to, or a motor operated valve near the gate can be controlled from a distant point, such as the power or gate house.

Overflow or bear trap gates are raised and lowered like a trap door, being hinged on the lower edge. Chains or cables are used to lift them. They are built very wide at some installations, where it is necessary to sluice large trees or cakes of ice.

Automatic rolling gates are not used very extensively. They are operated by the pressure of the impounded water. When the water rises the increasing pressure on the lower side of the gate turns it over, so that the water flows under it and above it until the head water reaches normal again, in which case the gate swings in the closed position.

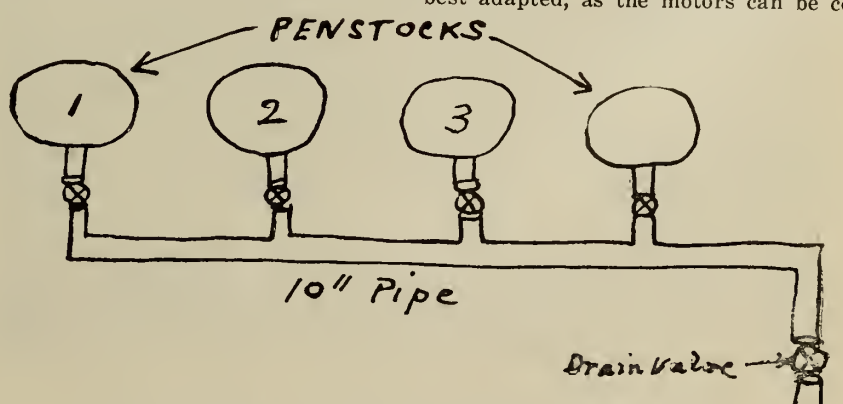
Automatic flashboards will be described as used at the spillway of one dam. The flashboards are similar to a bear trap gate hinged on the lower edge and controlled by rolling counterweights so arranged that the elevation of the reservoir rises only 3 inches when the battery of flashboards waste 12,000 cubic feet of water per second.

The counterweights are concrete cylinders 26 feet long and 3.25 feet in diameter and are fitted at each end with heavily geared rolling contacts, which roll on especially curved racks attached to the side of the piers above the crest. As the flashboards are lowered, owing to the pressure of the water the counterweights are forced up the incline by the pull of steel cables wound on a drum at either end of the counterweight and connected to the top of the flashboards. Hand-operated hoists are provided to manipulate the flashboards if a different reservoir elevation is desirable from that which the flashboards maintain automatically.

Butterfly valves are often called pivot valves. They are either hand, motor or hydraulically operated and are usually located near the bottom of a dam, like submerged sluice gates and gate valves. They will not freeze here unless exposed too much on the down stream side of the dam and waste a large amount of water for their size. One dam is provided with two butterfly valves 100 feet below the crest of the dam. They control the outlet of two 6-feet steel pipes and can be used to drain the reservoir, if necessary, as well as to waste excess water. At normal head water elevation they discharge about 1,500 cubic feet per second.

What has been said regarding gates in general will also apply to head gates which are located at the head of flumes, penstocks or tunnels.

Gates are placed at the head of a flume to regulate the water flowing into it. In this case electrical operation is best adapted, as the motors can be con-



ARRANGEMENT OF BYPASS CONNECTIONS TO PENSTOCKS.

trolled from the power house or by the use of a float switch.

At many developments filler valves are used to fill the penstocks before opening the head gates. These may be small valves or sluices built in the head gates or valves and piping arranged to connect an empty penstock to the forebay or an adjacent penstock which is full.

These valves serve a double purpose. First, they fill the penstocks slowly to prevent dangerous penstock pressures or water hammer. Second, they equalize the pressure on the head gate when the hoisting equipment provided is not capable of opening them under pressure.

The diagram shows how these valves may also be arranged to serve as drain valves when the pipe connections to the penstock are placed to drain the seepage from a closed head gate, thereby preventing this seepage from reaching the turbine where it would hamper the inspections or repairs under way.

When a penstock is filled the drain valve is closed and water is taken from any penstock which is full.

Where filler valves are not provided it may be necessary to open the head gate partly and then wait for the penstock to fill slowly, thus eliminating that high pressure and water hammer, as mentioned before.

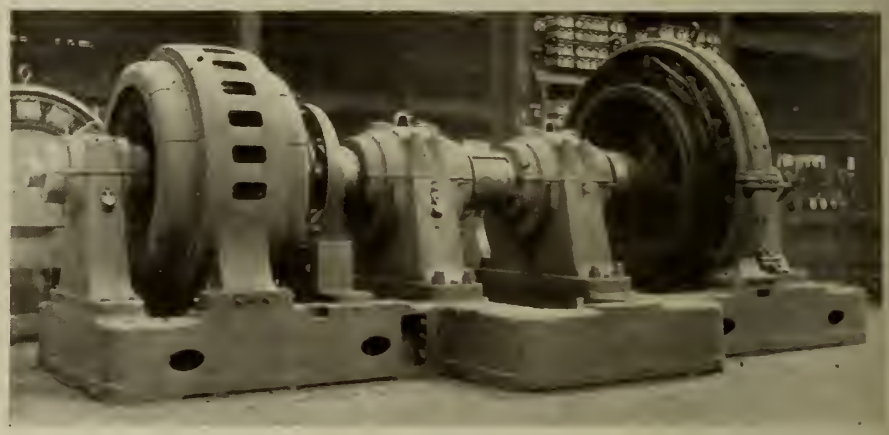
At one installation the gates are equipped with automatic control devices consisting of a limit switch geared to the sluice gate stems and a float actuated

(Continued on page 45)

New Universal Plate Mill

Technical Details — Construction Work—Electrical Equipment, and Various Other Features.

By J. H. Moore



THE FLYWHEEL MOTOR GENERATOR SET WITHOUT THE FLYWHEEL

THE universal plate mill just installed at the plant of the Dominion Foundries & Steel, Ltd., Hamilton, Ontario, will give Canada a mill of sufficient size to produce large plates, that heretofore have been imported through necessity. This mill, as already stated, is of the universal type and will roll universal plate from 7 inches to 41 inches, shear plate to 64 inches, and will roll both slabs and billets. At the present time all kinds of structural plates for bridges, buildings, cars, heavy pipe skelp, sheet bars, etc., are imported. These imports amount to hundreds of thousands of tons annually but the addition of this mill should help such work in our own country.

It is also intended to roll slabs and forging billets to furnish stocks for their own plow and jobbing mill, also their axle forge shop. These two departments have already been in operation for over two years. The new mill will also roll special forging billets or blooms, such as are used for locomotive, ship, and other heavy forgings. By removing the side rolls of the mill, sheared plates up to 64 inches can be rolled. It can also be equipped with blooming rolls for rolling billets, and a manipulator is installed to take care of this when used as a blooming mill.

At the close of the war this company found itself with a steel making capacity of over 12,000 tons per month; a large modern foundry; a heavy forge shop; a 22-inch bar mill; an axle shop, and a 26-inch jobbing mill. This latter mill was turning out soft center and solid plow steel, automobile frame steel, and jobbing plates, and it was realized that additional finishing capacity was absolutely necessary, not to speak of the need of equipment for the breaking down of the ingots for the existing finishing departments. After careful consideration, it was decided to install the plate mill about to be described.

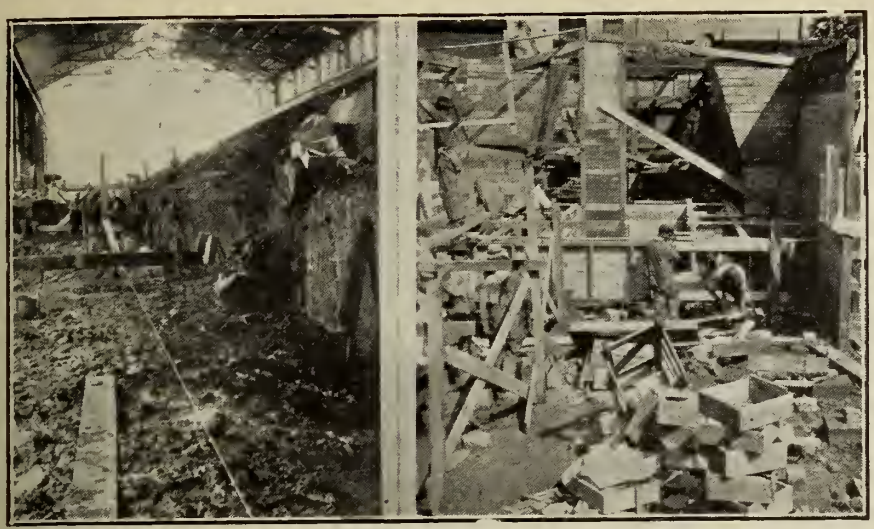
The mill itself is made by the Mackintosh & Hemphill Co., Pittsburgh, and is technically known as a 27-inch universal plate mill. The horizontal chilled iron rolls are 72 inches in length, with an extreme vertical lift of 20 inches. The vertical rolls both front and back are 18 inches in diameter, and have an opening range from 7 inches to 41 inches. The rolls are operated by hydraulic pull-backs, and the screw downs on the rolls are electrically operated. The main screw downs have two 60 h.p. compound wound motors in series, while for each set of side screws, there is a 40 h.p. motor of similar type.

The housings are cast steel of very rugged proportions, and many other principal parts on the mill are made from the same material. The pinions for both the horizontal and vertical roll drives are enclosed in oil type housings, and all these pinions have machine cut, helical teeth. The main screw down motors are mounted on the pinion housing cap, while the side screw motors are located in a pit at the side of the mill.

Provision is made for removing the side roll housings and inserting a short section of driven rolls both front and back, this allowing the rolling of shear plate up to 64 inches. This system of removing the side housings is also necessary when using as a blooming mill. The illustrations shown throughout the article are taken from various positions, and the details can be noted from the underlines.

Construction Work

It is of course easily understood that an installation of this size entails considerable preliminary construction work. Without even attempting to enter the details of the work involved, let us skim over for a moment a few figures that will show conclusively the magnitude of the task. The main building in which this mill is located is approximately 500 feet long by 68 feet wide. The tables for the mill run the complete length of the building, and reinforced concrete foundations for all these tables, shear, etc., had to be laid. Then there were the foundations for the different power plant units. All this meant considerable work, for it was absolutely necessary to trench down until good solid ground was reached. The inserted panel tells its only story in this respect. The construction views depicted illustrate a little of the work entailed, but we are making no attempt to touch this work in detail. Enough to say that the foundations are laid 14 feet down underneath the mill and of course tunnels are provided to allow workmen to attend to bolting down, repairs, etc. The amount of concrete used is surprising. Over 10,000 cubic yards of solid concrete has been laid and over 1,000 bolts have been used, these ranging from 1½ inches diameter up to 3 inches. A very notable



THE PICTURE TO THE LEFT SHOWS THE DIGGING OF TRENCH FOR TABLES, WHILE THE OTHER VIEW IS THE PREPARATORY WORK ON FOUNDATIONS FOR PORTION OF ELECTRICAL EQUIPMENT.

performance in continuous concrete pouring was brought to our attention, and the quantity poured is well worth repeating. In 2½ days 1,153 cubic yards were poured, this of course being for 24-hour days.

Electrical Equipment

The mill is direct connected to a 5,000 h.p. reversing motor of the compensating commutating pole type, and is specially designed to withstand the severe service encountered on reversing rolling mill work of this nature. The speed range of the motor is 120-0-120 r.p.m., and since the speed is quite slow during a considerable portion of the time, and the momentary current peaks are high, it has been designed for forced ventilation. A Buffalo Forge Co. fan is used, this equipment being placed in a lean-to at the side of the power house.

There is also a flywheel motor generator set, this consisting of a 2,000 h.p. wound rotor induction motor driving a 50,000 pound cast steel flywheel, and a special d.c. generator. This generator is also of the compensated commutating pole type and is designed to withstand the same peak load as the reversing motor.

The exciter set is of 3 piece construction, consisting of a 7½ K.W. exciter, and a 25 K.W. constant potential generator driven by a 50 h.p. induction motor. The magnetic control, main switch board, and air washing outfit are all located in the same building as the motor generator set.

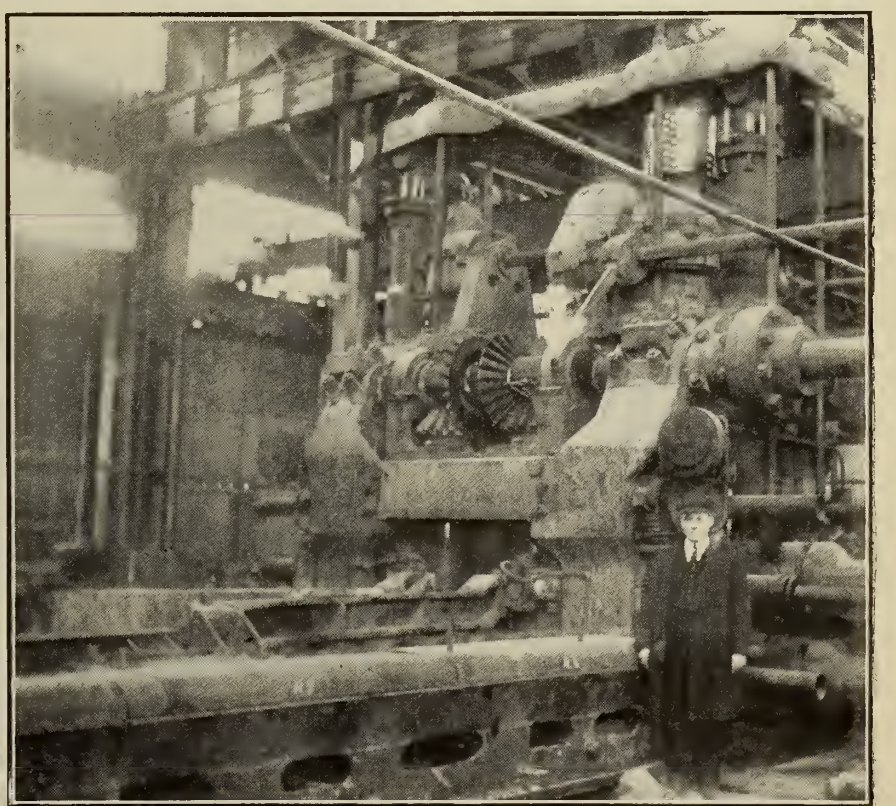
The switchboard and control apparatus is very interesting. The reversing motor is controlled automatically by magnetic switches. Adjustable relays control the rate of acceleration and retardation of the motor, so that it operates at a rate consistent with the reductions which are taken in the mill. The control is so interlocked that the motor always has full field when starting. Further increase in the speed, up to a maximum, takes place after the generator field has attained full strength.

The main switchboard controls the 2,000 h.p. A.C. motor, as well as the exciter and blower motors, and has mounted thereon the necessary meters for measuring the power of the different circuits. Two automatic oil circuit breakers are used between the power line and the primary of the 2,000 h.p. motor. One of these circuit breakers is for forward operation of the flywheel set, and the other breaker is for reversing the power to the set in order to make a quick stop when operating at full speed. This feature is included because it is sometimes desirable to bring the flywheel set to rest quickly, in case of trouble of any kind.

Between the D.C. generator and the reversing motor, an electrically operated high capacity automatic circuit breaker is used. The purpose of this circuit breaker is to interrupt the main D.C. circuit in case of very extreme overloads. The master switch is mounted in the operator's pulpit, and on an inclined panel in front of the operator is a D.C. ammeter and voltmeter for indicating the power transferred between the generator and reversing motor. This panel also has red and green lamps that indicate the position of the main circuit breaker.

The secondary of the 2,000 h.p. A.C. motor is controlled by means of an automatic liquid slip regulator. The position of the electrodes, and thus the amount of resistance inserted, is governed automatically by the torque motor, which in turn is actuated by means of a current transformer in the primary leads of the main motor. If the regulator is set for the average load on the motor during operation of the mill, it will take a constant input from the power circuit as long as the equipment is operating up to capacity. As peaks come on, the torque of the small motor is increased due to the greater current in the primary leads, which raises the movable electrodes inserting more resistance in the secondary. This allows the motor to slow down, and shifts the peak to the flywheel. After the peak has been taken care of, the input to the main motor will be maintained until the set is brought up to approximately full speed.

The excitation for both generator and motor is supplied by the small exciter



GENERAL VIEW OF THE PLATE MILL. F. C. WALKER, THE SUPERINTENDENT, IS A BIG MAN—BUT SMALL IN COMPARISON WITH THE MILL.

set. The direction of the roll motor excitation is not changed during operation, but is varied to meet the conditions of load and speed requirements. The operation is as follows: With the flywheel set at full speed, and master controller in "off" position, the roll motor will not be in operation, since the generator has no field current. The motor now has full field and the generator field is gradually excited, bringing up the voltage across the motor armature which will cause the same to revolve in the direction indicated by master switch. Compounding of the reversing motor is accomplished by means of the series exciter, which is excited by the current flowing between the generator and the motor. In this way any variation in the load on the mill motor will vary its total field excitation, thus giving the effect of a compound motor without the disadvantage of reversing such heavy currents in the series winding, which would be required in machines of the usual type. Due to this system, compounding can be varied to suit the operating conditions without the necessity of shunting heavy currents.

The speed at which the roll motor runs is practically proportional to the impressed voltage, independent of load up to full field on both motor and generator. From here, the speed is increased by manipulating the field of the motor. During the pass, the load on the generator is often very much in excess of the average over the entire cycle, and the automatic slip regulator enables the flywheel to supply the difference between the average input to the set and the load on the generator during the peaks. A slip regulator automatically inserts resistance in the secondary of the induction motor when its primary current reaches the average value, so that the speed of the set is reduced, allowing the flywheel to give up a portion of its energy. When the load on the generator decreases below the average for which the regular is set, this operation is reversed, i.e., the difference between output of induction motor and input required by generator goes to bring the set up to maximum speed. By this system, the input to the set may be limited to practically a constant value, independent of peak loads which are several times the maximum load on the line.

The roll motor is rapidly brought to rest by regenerative braking if the voltage on the generator is lowered below that corresponding to the speed of the motor. In pumping back power into the set, a large portion of the accelerating energy is reclaimed, helping each time to increase the speed of the set and consequently the energy stored in the flywheel. A device for accomplishing rapid acceleration is incorporated so that when it is desired to speed up the operation the normal time for building up the generator voltage can be reduced.

The incoming power is 13,000 volts, 3 phase, 27 cycle, and is brought through an underground cable 1,500 feet from the main substation of the company. It is transformed down to 2,200 volts immediately at the mill power house.

The power for screw down and table D.C. motors is furnished by a motor generator set consisting of a 400 K.W. generator 220 V.D.C. connected to a 590 h.p. synchronous motor 2,200 V, 3 phase, 25 cycle. This also furnishes the power for driving the D.C. motors on all tables, plate leveller, manipulator, furnace pusher, shear depressing table, punch rollers, etc. Provision is made for installing an additional motor generator set to duplicate this when required.

Various Details

The billet shear used is of Mackintosh & Hemphill design, and was built by the Canadian Allis-Chalmers Co. The capacity of the shear is 10 feet by 10 feet square, and slabs up to 40 inches width can be cut. The stroke is 12 inches, the length of knife 48 inches, and the number of strokes 14 per minute. It is driven by a 125 h.p. induction motor and the clutch shifter is worked by a 9 h.p. D.C. mill motor with brake and limit switch. The shear gauge is also of M. & H. design, and is operated by a 9 h.p. D.C. motor.

The shear depressing table, back of the shear, is 23 feet long with 11 rolls 14 inches by 48 inches. It is driven by a 60 h.p. D.C. mill motor at a speed of

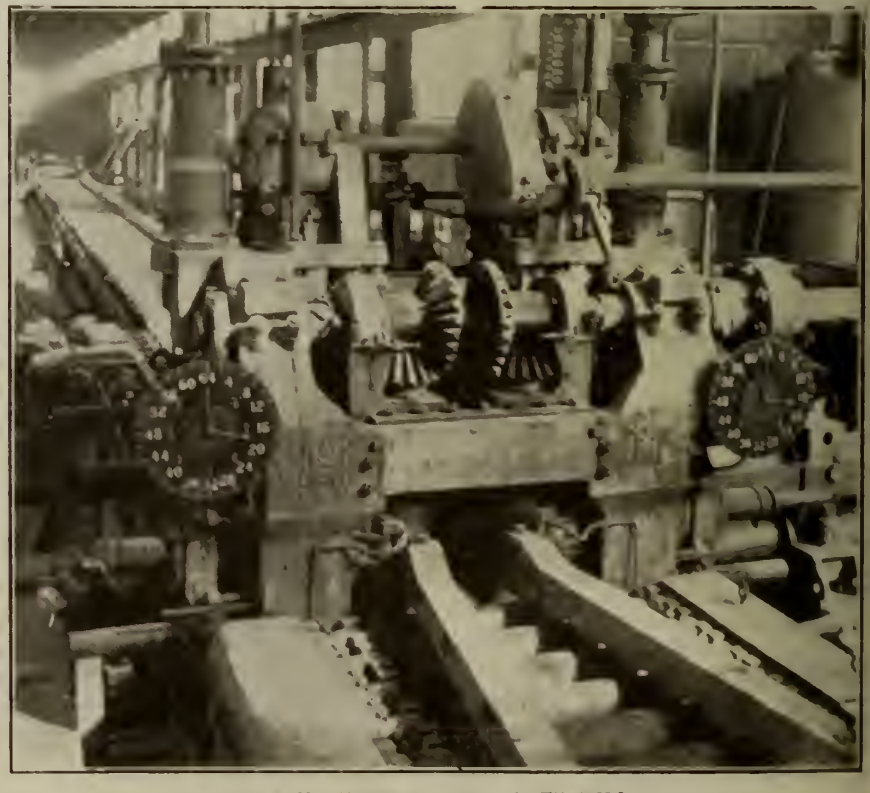
SOME VIBRATION

F. C. Walker, plate mill superintendent at the plant we are speaking of, tells a funny story about vibration. "You are, of course, well aware," he started off, "that a plate mill of any size is always subject to considerable vibration, but you have to actually experience the sensation before you have any conception as to its extent.

"When you stand on the pulpit, or as some might term it, the control bridge, you feel the sway to a nicety. I remember on one occasion the foundations were none of the best, and the vibration and swing was worse than usual. It was like standing on the bridge of a ship during a rather nice swell.

"On reaching home that night I could still feel the sway, but the limit came when I actually woke up in the night to find myself grabbing the bed post firmly in order to keep myself from falling off the pulpit."

The little tale about vibration may seem to the uninitiated as exaggerated, but when we consider that the firm installing this plate mill at Hamilton saw fit to have a 14-ft. deep foundation of reinforced concrete, there must be something to the story. Below the concrete again there is placed considerable piling to a still further depth of 30 ft., this, of course, being to prevent sinking. Good, firm soil must be reached before the foundation proper is poured. In the old days these were of stone, not concrete, but were never as satisfactory as the modern method. Before a foundation is commenced, the ground is carefully drilled to ascertain its quality at different depths. Having this information at hand, they can proceed to drive their piling.



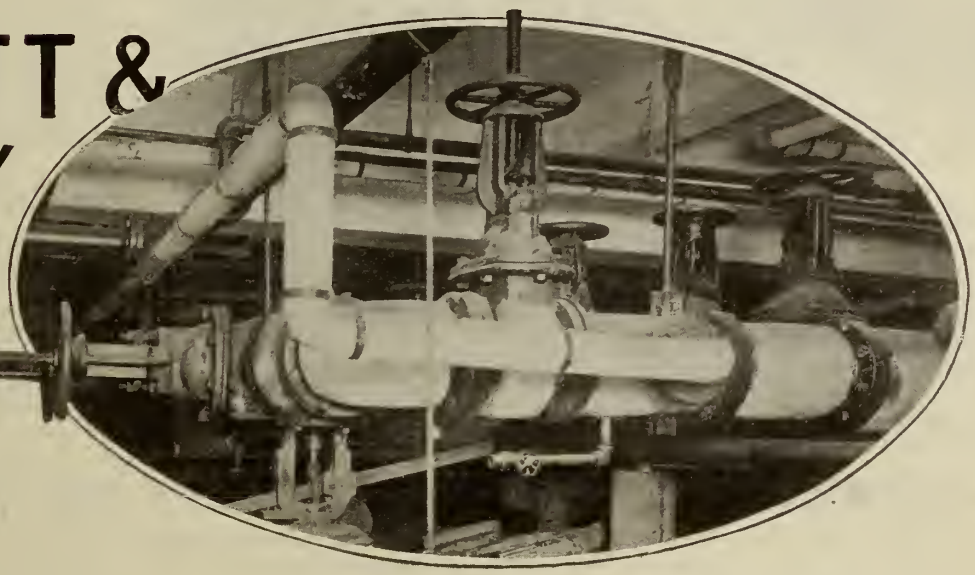
CLOSE UP VIEW OF THE PLATE MILL.

Lessen Maintenance Costs With

PRATT & CADY

Renewable Seat Ring

Valves



You can insert a new set of seat rings for about 10 per cent. of the cost of a new valve. This is why Pratt and Cady Valves are so economical. And you can put in new rings without removing the valve from the line. Pratt and Cady Valves are double seated so that pressure can be applied at either end. They stand the hardest service. Write our nearest branch for further information and prices.

Durabla Packing

saves money in any power house

Durabla Asbestos Sheet Packing effects big economies because it meets every packing requirement. With Durabla, only half the usual thickness is required. It does not deteriorate in stock, and when properly fitted may be used again. Durabla is not affected by contraction, expansion, condensation or excessive vibration. You save money by using Durabla on every flange joint. Our nearest branch house will gladly submit specifications and prices.

THIS ILLUSTRATES THE 5,000 H.P. REVERSING MOTOR WHICH DRIVES THE MILL.

266 feet per minute. The shear run out table is 45 feet long with 27 rolls 14 inches by 48 inches and is driven by a 60 h.p. D.C. mill motor running at a speed of 266 feet per minute.

The punch rollers are located immediately back of the shear run out table and are 18 inches by 48 inches. These rollers are for delivering skelp, etc., to the piler, the intention being to cut skelp sheet. bar, etc., on the billet shear without going over the hot bed. The speed of rolls is 480 feet per minute.

The shear equipment consists of a cut-off and two side shears with an arrangement of c stor beds to serve them. A 10-ton platform scale 5 feet wide and 50 feet long is also arranged for castors.

On account of the variety of products, a diversity of heating furnaces is necessary. A 32-foot continuous furnace with double electric charging pusher and delivery pusher places the ingot directly on to the approach table.

The mill tables, front and back, are 35 feet long, each having 20 rolls. The 13 rolls next to the mill are spaced 17 inches, while the balance are spaced 21 inches. All rolls are 14 inches diameter, 72 inches long. The maximum speed of table is 428 feet per minute. The case, and the table beams are made of cast steel and the roll bevel gears, as well as the drive gears, are machine cut cast steel, running enclosed in oil.

Each mill table is driven by two 80 h.p. mill reversing motors, connected in series. These motors have full magnetic plugging control, and are so arranged that the motors on the incoming table work at half speed, while the outgoing table works at full speed in either direction.

The two controllers are mechanically connected, and the operator uses only one handle to operate all four motors. This is accomplished on the first point of the master controller in either direction, and on the second point both tables run at full speed.

The approach table is driven by a 60 h.p. motor. The length of this table is 70 feet and it has 35 rolls spaced 18 inches centers in front of furnaces; while the balance are spaced at 21 inches and 30 inches centers, the latter distance being at the extreme end of table. The speed of this table is 350 feet per minute. There is also an extension to the table, this being 55 feet long, but with no rollers.

The run out and hot bed tables are each 145 feet long, the former having 58 rolls and the latter 61. These rolls are 14 inches diameter, 59 inches long and the center distance between the rolls is 30 inches. As on the other tables, the gears have machine cut teeth and run in oil. The speed of the rolls is 350 feet per minute. Each of these tables is driven by two 60 h.p. mill type motors connected in series.

A plate leveller is situated between the run out and hot bed tables, and this is a nine roll machine made by R. S. Newbold. The rolls are 10 inches diameter, 72 inches long and their speed is 158 feet per minute. Motor drive and screw down are of course provided. Extended shoe plates are provided to allow for removing leveller and inserting a dead roll when rolling slabs or billets.

A second continuous double skid furnace is installed alongside the first furnace, and is equipped with a hydraulic pusher. This will handle larger bloom. and ingots up to 50 feet and the pusher will deliver material directly to the table. The capacity of both these furnaces is about 4,000 to 6,000 tons respectively.

It is the intention ultimately to make provision for four soaking pits, two to be installed later, but the first pits are four hole 6 feet by 9 feet with hydraulic operated covers. These pits are arranged for oil firing with provision for producer gas later. The soaking pit building is located immediately adjoining the furnace building, with the approach table through center, having two pits on each side.

The buildings in which these units are housed are of steel construction and provision is made for extending shipping room as required. The main building extends across the other buildings and is partitioned off from the power house

PARTIAL VIEW OF TABLES AND MILL. NOTE—THE AUTOMATIC SWITCHES ARE IN THE GLASS-PROTECTED BUILDING TO THE LEFT OF THE TABLES.

"KYMBALA"

AN IDEAL JOINTING

IT would be folly to contend that no further improvement is possible in jointing material, but "Kymbala," manufactured from Blue or South African Asbestos Fibre, is now widely admitted to be a great improvement on all Jointings hitherto manufactured. Its advantages may be summed up as follows:

PURITY.—Blue Asbestos contains only 4% impurities against 15% in the best White Asbestos Fibre.

TOUGHNESS.—Blue Asbestos is of double the tensile strength to White Asbestos.

PRESSURE-RESISTANCE. — Blue Asbestos Fibre is admittedly the hardest and most resilient Asbestos Fibre extant, besides being water and steam-resisting, and can absolutely be relied upon not to "blow out."

DURABILITY.—Owing to its great purity, strength and pressure-resistance, it has proved to last easily more than double the time of other high grade jointing, thus considerably reducing stoppages, labour and material.

WEIGHT.—"Kymbala" is the lightest Jointing, hence means a reduction in cost. Put it to the test, you'll find it the best in every way.

Samples for trial will be supplied on application to the sole Manufacturer

BELTING

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto. (p.f.h.)

MACHINERY WANTED

EQUIPMENT WANTED—550 H.P. CORLISS type steam engine; 250 H.P. Corliss type steam engine; 36 or 42 Corliss iron planer; wood turning lathe pattern maker's type (all iron); boilers, small and large. The Andrew S. Forman Co., Reg., Room No. 60, 232 St. James St., Montreal, Que.

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House." (p.f.h.)

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS VACANT

WANTED AS ASSISTANT EDITOR, ON group of technical papers, live-wire mechanical engineer. Qualifications required are: Age, under 45, good education, certain amount of practical experience, ability to express ideas on paper, good mixer and aggressive worker. Splendid opportunity for the right man. State full particulars in first letter, mentioning present salary. Box 200, Power House.

PERMANENT POSITION OPEN FOR EXPERIenced power-house shift operator, familiar with hydraulic plants; location North-Western Ontario. Only experienced men need apply, mentioning "Power House," to Employees' Relations Department, 190 University Ave. (pfh)

EMPLOYMENT DESIRED

ENGINEER-MILLWRIGHT, 3rd CLASS, MARried. Wants position. References. Apply Box 201. Power House. (pfh)

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers. Corliss and all classes of stationary engines, compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St., Toronto. (pfh)

MACHINIST—WITH DRAUGHTING EXPERIence, wants work of any kind. N. Ryckman, No. 174372, 5 Foxley St., Toronto. Phone Parkdale 3254w. Mention "Power House." (pfh)

MECHANICAL ENGINEER, 29, FIRST-CLASS stationray engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House. (pfh)

EQUIPMENT

STEAM ENGINES, BOILERS, HEATERS, tanks, stacks, pumps and condensers, transmission and elevating machinery, safes, vaults and vault doors; catalogue and specifications sent on request. Apply, mentioning "Power House," to Goldie & McCulloch Co., Ltd., Galt, Ont. (pfh)

PORTABLE BOILERS—LOCOMOTIVE TYPE, on wheels, each 15 horsepower, with engines mounted on boilers; can get Government certificates for 90 and 100 pounds working pressure; cheap; also 40 horsepower, high speed Leonard automatic engine. Apply, mentioning "Power House" to Henry Engineering Co., 71 Bay Street, Toronto. (pfh)

BOILERS AND POWER PLANT EQUIPMENT bought by the Henry Engineering Company (Henry-Rumgay-McBryde), 71 Bay St., Toronto. Mention "Power House." (pfh)

NON-CORROSIVE CYLINDER OIL MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 242 244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

Patterns *Machine Work*

The power house walls are reinforced concrete and glass with gypsum slab roof and concrete floor. The mill building and power house are served by a 40-ton crane, while other cranes in the plant are of 10-ton capacity.

With the exception of the mill and plate leveller, all the tables, shear pushers, punch roller, and accessory machinery was built in Canada. No doubt readers will remember our Jan. 8th issue in which we told of the work being done for this mill by the Dominion Steel Products Co., Brantford, Canada. The steel castings for the work performed in Canada were supplied by the Dominion Foundries & Steel, Ltd., from their own foundry.

The idea of producing as much as possible in Canada is to be commended, and here is how the work was distributed. The tables, including shear depressing and furnace pushers was made by the Dominion Steel Products, Brantford, Ontario, the shears by Canadian Allis-Chalmers, Toronto; manipulators by John Inglis, Toronto; buildings by Hamilton Bridge Works, Hamilton, Ont.; while the electrical equipment was supplied by the Canadian Westinghouse Co., Hamilton, and the Canadian General Electric Co., Peterboro, Ont.

A good feature of this installation is the railroad facilities provided. Three railway tracks serve the billet yard, shipping department and mill building, while a track runs right into the building at one point.

Briefly stated, the addition of this mill should mean much to Canadian business generally. Billets and blooms from 3 inches by 3 inches to 8 inches by 8 inches, slabs from 2 inches to 8 inches thick and from 6 inches to 40 inches wide are now available, while skelp of all sizes and weights 8 inches and wider can be made. Sheet bar (for sheets) of all sizes and weights can be produced, and universal plate from 7 inches to 41 inches of any thickness and length can be made. In addition to this list, sheared plate 66 inches wide, and of any thickness can be procured. The capacity of the mill being 150,000 tons per year will allow them to handle the demand easily. In fact, when in full swing this installation will be one of the largest steel finishing units in Canada.

Want Guarantee.—The National Shipbuilding Company, of Goderich, which was organized in 1917 to build trawlers to the order of the British Admiralty for use in the North Sea, are asking the town council of Goderich to guarantee a bond issue that has been created on the property and assets of the company. The organization is perfecting and manufacturing a flax-pulling machine of the Vessot model, on which the patent rights are held both in Canada and abroad. Marine engines and boilers were made for the Imperial Munitions Board, the French government and the United States Emergency Fleet Corporation. Before the shipbuilding industry began to subside, the National Shipbuilding Co. turned its attention to the manufacture of the flax-pulling machine. In asking the municipality to guarantee the bond issue, the company points to its record including wage payments aggregating $400,000 for three years and nine months ending December, 1920.

REGULATING OVERFLOW IN HYDRO

Continued from Page 38

by the water in the penstocks. When the gates are opened enough so that the penstock can be filled in 5 minutes, the limit switch opens and stops the motor and another limit switch prevents over travel. The gate is closed by reversing the control switch at the power house and a limit switch again stops the motor when the gate reaches its closed position.

In order to facilitate handling or to save head room in gate houses, sluice gates may be built in detachable sections, in which case cranes or hoisting winches are used to handle the gates. When a failure of the turbine governors will result in dangerous over speeding it may be desirable to have the head gates close automatically. This may be done electrically with a centrifugal switch. Tripping ropes from the head gates may also be arranged so that an operator can trip any head gates from the power house, the gate closing by gravity.

When gates are remotely controlled the gate opening can be shown with suitable signal lamps.

At one plant in Canada two timber flap gates are used to close each half opening of the entrance to a penstock. These gates differ somewhat from the ordinary, as they are hinged at the bottom and are provided with concrete counterweights at the top, which keep them open under normal conditions. They swing in a manner similar to a wagon box end gate, and when open they rest on a concrete sill at an angle of about 45 degrees from vertical, so that hoisting can be done easily. As all parts of these gates are submerged below the point of freezing they make very good gates for a cold climate.

Steel gates are also built in this way and at one plant the power house crane handles them.

Two sources of power for handling gates which have not been mentioned are gasoline engines and small water wheels. At one place I know of a gasoline engine is used to operate the gates at the intake of a long flume, while at another place gates are handled with a 25-h.p. water wheel, clutches being provided to connect the gate to a long shaft, which is driven by the wheel.

A new industry has opened a factory at Selkirk, Man., and is known as the Canadian Insulation Company. The head office is in Winnipeg.

TRADE GOSSIP

Brantford Firm Changes.—The Brantford Machine & Tool Co., Ltd., has just been incorporated to continue and add to the former business of the Brantford Machine & Tool Co. Mr. Wm. J. Ham, a son of Mr. Jos. Ham, of Ham Brothers, has taken an interest in the concern and will take an active part therein. In addition to their old line of machine and machine tool work, they intend extending and manufacturing a line of garage equipment, such as bench presses, boring tools and small air compressors, and expect to find quite a ready market for same.

A large British factory, which was erected during the war chiefly for the production of "dope" or varnish for aeroplane purposes, is turning its attention to the application of these and other products as peace time products. It has been found that this aeroplane dope makes an excellent insulating varnish for electrical machinery. Further, paper strips drawn through the solution become impregnated with it and are then suitable for winding on copper wires to make "paper-insulated" cables for telephone and electric power purposes. Artificial silk, which can be braided on to wires instead of the natural silk, is also produced; and still another possible line of development is in the molding of electrical connections in celluloid, which has a very high electrical resistance and is non-inflammable even when exposed to the heat of a fierce flame. All these products are "synthetic"; that is to say, they are built up by chemical processes from simple constituents.

NEW CATALOGUE

The Ross Heater & Mfg. Co., Inc., Buffalo, N.Y.—Catalogue F, dealing with the Ross heater. This heater is of the closed or tubular type. They are used for heating all kinds of fluids and the customary heating medium is steam. The common liquid heated is water, but oil, sugar juice, chemical compounds, or any other liquid can be heated. There are two types of heaters, instantaneous and storage. Various photographs, specifications and sectional views are given in this catalogue.

The Hanna Engineering Works, Chicago, Ill.—Catalogue No. 3. A very complete catalogue dealing with compression yoke riveters; 48 pages are filled with real, live information, showing details of construction, specifications and completed riveters of various types. This concern have also sent us a book of instructions that should be in the hands of anyone operating one of their riveters. It is full of practical and valuable hints that should save any trouble in operating, not to speak of obtaining maximum production. They also have a catalogue No. 10 that deals with their line of foundry moulding machines in splendid detail.

Terrell's Equipment Co., Grand Rapids, Mich.—A catalogue describing their line of steel cupboards, wardrobes, lockers, shelving and bench drawers. Different arrangements are shown and all dimensions of the various sections are stated.

Jones "A-C"

High-Duty Stoker

Labor Saving
+Coal Saving
-Maintenance
=Actual Economy

An Important Deduction

Never forget upkeep—that all-important deduction—in choosing a high-duty mechanical stoker. Only real—not theoretical saving—makes a stoker installation pay dividends.

The big yearly saving of the Jones "A-C" Stoker is practically *net,* for it is not cut into excessively by maintenance costs.

The Jones is the simplest of high-duty multiple retort stokers. The one moving part within the furnace—the pusher rod—is buried deep in the green fuel where there is no possibility of it burning out. There are no moving or wearing parts in contact with hot coal. And all wearing parts are heavily built of materials that insure long life.

The simple, driving mechanism eliminates the use of driving shafts, bearings, gear boxes, gear shift devices, hand shift clutches, chains, levers, shearing pins, etc.,—complications that always mean high maintenance, if not frequent shut-downs.

Retorts and tuyeres are so constructed and placed that the under side is fully exposed to the air in the air pit, and consequently properly cooled. The entire bottom sides and end of each hollow tuyere block are exposed to the air so that burned-out tuyere blocks are uncommon.

Is it at all surprising that the repair cost in a representative "A-C" equipped plant averaged *only one cent per ton of coal* burned?

Because of this extremely low maintenance, the unchallenged ability of the Jones "A-C" Stoker to effect still greater economies in burning Canadian coals, makes it the logical choice for Canadian plants of every size.

Where shall we send your copy of the new catalog?

The Under-Feed Stoker Co. of Canada

Which Way for You-

25c. for a new seat ring or disc---
Or $2.50 for a complete new valve?

About 99% of valve wear comes on the seat ring of a gate valve and on the disc of a globe valve. Looking that fact in the face, doesn't it strike you as absurd and wasteful to have to throw away an entire valve merely because one small part of it has worn out?

Pratt & Cady Renewable Valves eliminate this big waste.

If a leak develops, you simply take out the worn seat ring or disc and slip in a new one. The whole operation takes only a jiffy. You don't even have to remove the valve from the line—which makes a considerable saving in labor cost on top of the other saving.

This gives you a good-as-new valve at approximately one-tenth the cost of a new old-style valve. Write for catalog.

Improve the Efficiency of Labor Cut Down Coal Consumption

Now is the time to improve the all round efficiency of your plant by relieving your men of the tedious drudgery incidental to hand feed water regulation, or the constant watching, adjusting and other attentions required by ordinary regulators.

Give your men a chance to use their hands and brains to cut down coal consumption by inspecting, testing, and studying the results of present operation and then making improvements that make for greater economy and increased efficiency.

The regulation of the feed water can be done much more scientifically, economically and reliably by

Ten hours! More than a day's labor! Think of the cost in dollars!

Such was the result of a test between the flexible type of hack saw and an all-hard blade.

Both were designed to cut the same material! Both were carefully run to deliver the utmost service, but the all-hard blade demonstrated from the start that it cut costs by cutting quicker. On power sawing, where weight is needed to make the teeth of a blade "bite" into the stock, the soft-back saw is not practical. Because of its flexibility, pressure makes it "buckle" Without this weight the cost per cut is too high.

For economical power sawing the proper blade for the particular kind of material to be cut is indicated by the Starrett Hacksaw Chart. It will be mailed to you, free.

A Stirring Instalment of Heming's Famous Story

ARTHUR HEMING continues his remarkable story of Canada's Northland in March 1 MACLEAN'S MAGAZINE. In "Wild Animals and Men" he tells how he and Oo-Koo-hoo tracked and trapped wolverine, lynx, and other wild animals, and tells fascinating stories of battles of wits between the hunters and the hunted. The wiles of the Indians and half-breeds are pitted against the amazing, almost superhuman craftiness of the animals—and sometimes the denizens of the forest wilds outwit their human antagonists.

Fun at Opening of Parliament

J. K. Munro sat in his seat in the Press Gallery, Monday, February 14, when Parliament opened, and looked down with the good-natured tolerance and contempt of an iconoclast and a satirist at the proceedings. The members invariably amuse "J. K."; it takes a really big man to elicit more than scant praise from his sophisticated pen. His March 1 article is entitled: "Funny, as the Owl is Funny."

Other Big Features and Fiction

"Canada's Fur Future," by Agnes C. Laut. Telling what a potential gold mine Canada has in her fur industry, properly conserved and exploited.

"Goldwin Smith," by James Mavor, Ph.D. The personal side of the "Sage of the Grange," the man who was tutor to King Edward VII, before coming to Canada.

"More Political Memoirs," by Col. George H. Ham. Further stories of the "Solons of the Eighties," and Ottawa 30 or 40 years ago.

"Pawned," by Frank L. Packard. The story of a triple regeneration—in this instalment John Bruce declares his love for the "Pawnshop Girl."

"The Man Who Knew Too Much: The Bottomless Well," by Gilbert K. Chesterton. This Near-Eastern well and a revolving bookcase figure in a baffling murder story, handled by England's master of fiction.

"The Lady at His Door," by Barker Shelton. A girl takes a law course, graduates—but that doesn't mean clients. But she gets a partner—and for life.

"The Millionth Chance," by Henry Holt. An Adventurous sea story, with a girl skipper and a man who won her respect—and even her love.

"CANADA'S NATIONAL MAGAZINE"

We make Boilers—all Types—Plate Work—Pulp Mill Machinery, etc.

Have Faith in Canada

Canadians are a nation of workers—

We have the cream of the world's natural resources—

We have to-day the largest per capita purchasing power of any nation in the world—

We have to-day the largest per capita savings funds of any country in the world—

Normal efficiency of Canadian labor is being rapidly restored—

Canadian production per farm compares favorably with any other country in the world—

Exhaustion of stocks amongst retailers and wholesalers is everywhere apparent.

Available funds for business enterprises are accumulating in millions.

Will you do your bit to put the needed new life into business?

BUY WHAT YOU NEED—NOW

A Plain Question

What is the Canadian National Newspapers and Periodicals Association?

And a Frank Answer

For many years prior to December, 1919, all the publications in Canada practically were grouped in one Association, known as the Canadian Press Association. In this Association there were three sections, Daily, Weekly, and Trade and Class. A little over a year ago it was mutually agreed by the publishers comprising these three groups that more effective work could be done for and by each section if separate organizations were formed, and, coincident with that decision, there came into being the

Canadian National Newspapers and Periodicals Association

In this Association there are incorporated the following classes of publications:

Agricultural newspapers
Business newspapers
Educational newspapers
Religious newspapers
Technical newspapers and Magazines.

Membership in the Association involves certain obligations. Every paper admitted has subscribed to ten rigid Standards of Practice, the purpose of which is to afford ample protection to both the subscriber and the advertiser. Every publisher pledges himself, before he is permitted to enjoy the benefits of membership, to

"Consider first the interests of the subscriber," to

"Work for truth and honesty in all departments," and, among other things, to

"Supply advertisers with full information regarding character and extent of circulation."

These are only a few of the conditions which have to be subscribed to precedent to admission to the Association, but they will give an idea of the high standard demanded.

There are already embraced in the membership of this Association a very large majority of the reputable and responsible publishers of the newspapers and magazines classed above, and it is believed that within a very short time, practically all that are eligible—all who can conscientiously endorse the Standards of Practice — will have been enrolled in our membership.

List of Members

The publications listed below—all of them members of the Canadian National Newspapers and Periodicals Association —should be given preferential consideration in the planning of an advertising campaign. They embrace mediums which appeal to the consumer (either city or farm dweller), merchant, business executive, purchasing agent, technical man, etc. The combined purchasing power of the readers of these papers is greater than that of the total of all other classes of publications in Canada. The facilities of the office of this Association are at the disposal of any firm planning an advertising campaign. We may be able to give you information that will make your advertising dollar buy better value.

Constant Watchfulness

The Hays Automatic CO₂ and Draft Recorder maintains a constant watch over all the conditions which effect furnace efficiency, keeping a positive record of performance upon which improvements in practice may be based.

This automatic record helps the fire room force to attain the highest efficiency and hold it. It makes good results a continuous matter, which is more important than spasmodic changes. Firemen like it, for improved methods mean better results with less work.

Complete description of the advantages to be gained in your plant will be sent upon request.

ARE YOU WASTING MONEY?

You are if you use that class of packings that fade away almost at fast as you apply them.
REASON:—They are made of a low grade of short fibre asbestos, requiring cotton to hold them together, thus limiting the packing power to resist heat.
You can secure the full money value from your packing if you use

TRADE MARK
"PALMETTO" PACKING
REG U S PAT OFFICE

as it is made strictly of long fibre asbestos of the first grade and thoroughly lubricated.

USE THE BEST PACKING AND YOU ARE NOT CONSTANTLY REPACKING THE STUFFING BOXES.

If you don't know the great lasting qualities of "Palmetto" let us send you a free working sample—it will convince you.

Insure Constant Level

The most economic way to operate boilers is with constant water level and uniform constant inflow. With the level held constant at middle gage, the greatest amount of heating surface is presented to the hot gases and the maximum amount of steam space is available.

Vigilant Feed Water Regulators

meet these conditions in a very satisfactory way.

They are easily adjusted to maintain an absolutely constant water level at any arbitrarily determined height in boilers, and they feed continuously with perfect uniformity.

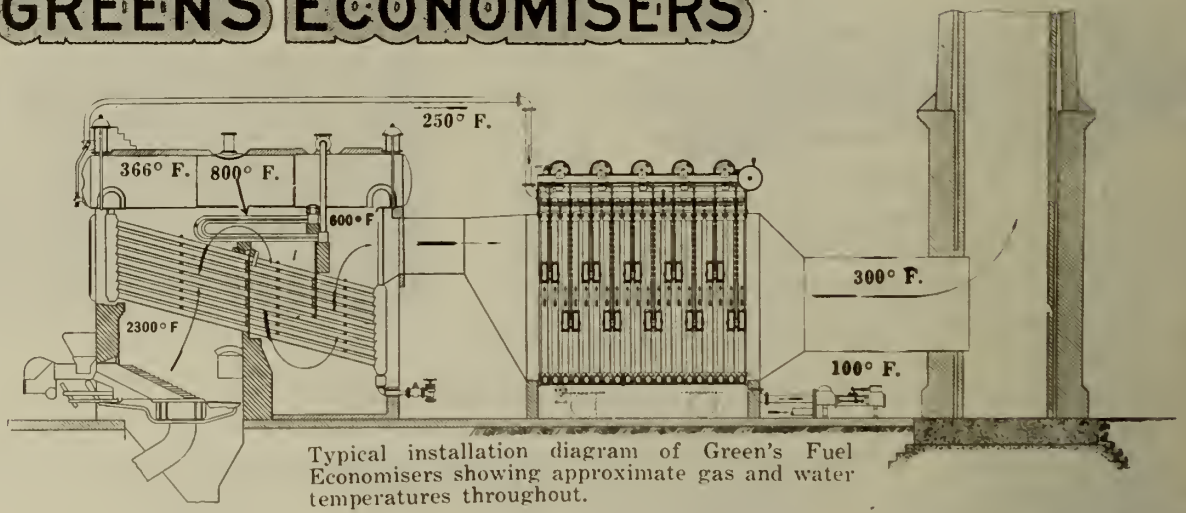
GREEN'S ECONOMISERS



Typical installation diagram of Green's Fuel Economisers showing approximate gas and water temperatures throughout.

At the recent Chemical Exposition in New York, during the fuel economy conference, one of the speakers, a noted engineer, stated that by far the greatest heat loss in the boiler room was in the sensible heat of the exit gases.

The use of extra boiler surface to cool gases below 500° F. does not pay because below 500° F. the heat absorbed per square foot of heating surface does not equal the cost of maintenance. The use of **Green's Economiser** is the **most economical method** for recovering this loss—it will reduce the gas temperature to a low figure at minimum cost—by transferring the heat of the gases to the feed water, under boiler pressure, thus allowing the boiler to be supplied with water at a temperature slightly lower than the steam itself.

Write for our bulletin No. 151, or call for one of our engineers to inspect and make recommendations for your conditions.

GREEN'S ECONOMISER, LIMITED. TORONTO

Money-Saving Information

"The most useful information contained in any paper I get"—so a Western banker writes in to-day's mail, renewing his subscription for FINANCIAL POST.

"Very often," his letter goes on to say, "I am called on to suggest investments for small amounts, sometimes as low as a few hundreds, and I find your Investors' Inquiry Service a reliable partner to consult. If every investor knew there was such service at his call it would surely lessen the losses of many of these people."

The Investors' Inquiry Service fills just that need. Unless you are perfectly sure of your investments write us before you buy.

It costs FINANCIAL POST subscribers nothing to be sure before placing hard-earned savings in stocks that may never have a chance of paying dividends. Trained service men will give you the benefit of keen analysis based on the facts behind the securities you are considering. This is one of many features enjoyed by our readers.

THE FINANCIAL POST 143 University Avenue, TORONTO, CANADA

Send me for one year (52 issues) The Financial Post. I attached $5.00—commence at once.

Mr. Engineer, are you—

one of those wide-awake, up-to-the-minute engineers who is willing to be shown how economies can be effected in the boiler room? Many power plants in Canada and the United States, especially noted for high operating efficiency, consider "Bailey" meters essential to the best operation of either coal or oil-fired furnaces.

Bailey Boiler Meters

"Bailey" Boiler Meters — the coal savers—record the true relation between the coal and air supply to the furnace and plainly show the men what adjustments to either are required to maintain high operating efficiency and economy.

CHARTS SHOW PERFORMANCE OF INDIVIDUAL BOILERS

and tell when a boiler requires cleaning or inspection for leaky tubes or broken baffles. You can check the work of the fireman at all times.

Try one "Bailey" Boiler Meter and you will soon order "Bailey" equipment for all of your boilers.

May we send full details? Tell us your requirements.

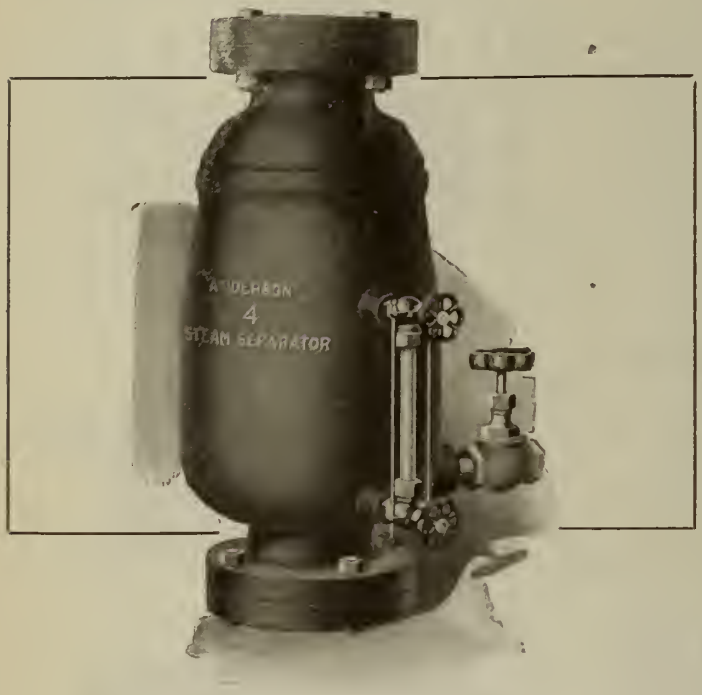
ANDERSON
Steam Separator



An Insurance Policy

You take out an Insurance Policy to safeguard and provide in case of accident. You use an Anderson Steam Separator to safeguard and prevent accidents from occurring. Yet there's quite a similarity, for an Anderson Steam Separator is a positive insurance against engine breakdowns due to accumulated moisture in engine cylinders and turbine casings.

The Anderson delivers **dry steam** under all operating conditions. Its improved construction places it in the foreground for efficient operation.

A copy of catalog fully describing all Anderson Power Plant Specialties will be forwarded on request.

The V. D. Anderson Co.

Diamond Soot Blowers Mean Greater Profits

THE big central stations place a definite re liance upon Diamond Soot Blowers to ear dividends. They know that to pay real pro fits they must cut the cost of producing power t a minimum. Their very existence, as a matter o fact, depends upon efficient, economical plan operation.

With perfect unanimity of action the big centra stations have adopted as one of the fundamenta principles of efficient boiler operation the rul that all boiler heating surface must be kept fre of soot and ash deposits, clean as only Diamon Soot Blowers can make them.

The illustration at the top of this pag shows one of many Diamond installations at th Union Electric Light and Power Company's S Louis plants. Among hundreds of other centr station users of Diamonds the following a typical:

Buffalo General Electric
Beech Bottom Power
Detroit Edison
Appalachian Power
Philadelphia Electric
Southern Power
Scranton Electric
Erie Lighting
Haverhill Electric
Central Illinois Public Service

Whether you operate a central station or industrial power plant your 1921 profits will seriously affected if you do not keep your boile in first class, efficient condition. Diamond Soot Blowers will increase your dividends out of proportion to the cost of the equipment.

U.S.PAT.OFFICE

COPPUS TURBO BLOWERS EFFECT STEADY SAVINGS

In the modern plant of the New York Ice Company, New York City, this 22" COPPUS Turbo Blower has been saving time, money and labor ever since installation in April, 1917. It has **made possible** the use of cheap fuel, and **made sure** the maintenance of constant steam pressure. So satisfactory has been the service of this COPPUS Blower that two more blowers have since been purchased for other plants of the New York Ice Company.

COPPUS Turbo Blowers are cutting down fuel costs and keeping up steam pressures in cold storage and artificial ice plants all over the country. Automatically regulated, self-oiling, quiet-running—COPPUS Turbo Blowers are by far the most efficient means of securing mechanical draft.

Let our engineers tell you just what COPPUS Blowers can save you in your boiler room. Write for Blower Catalog

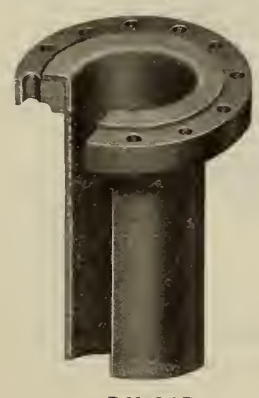
P H FLANGED PIPE JOINTS

SCREWED



P.H. LAP

P H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

This Big Southern Company Uses 14

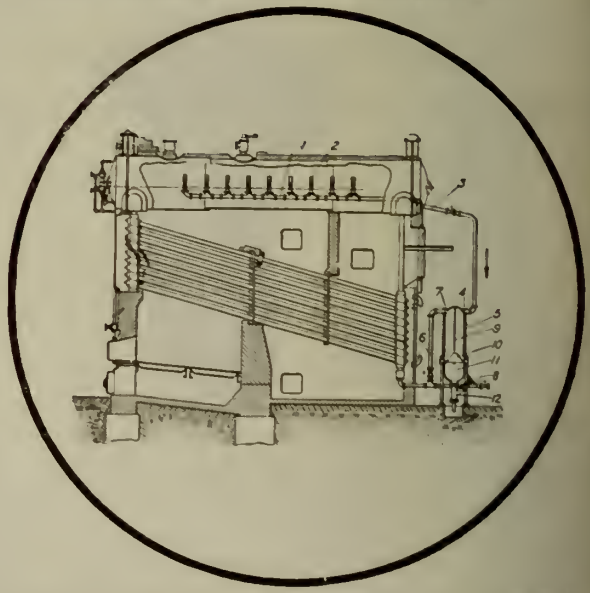
The Union Seed and Fertilizer Company, which operates a great many plants throughout the South, has installed 14 YARWAY BOILER SKIMMERS. Their initial order was for one Skimmer on sixty days' trial; now they order them in lots of three and four. The illustration shows a skimmer operating in their Columbia, S. C. plant.

The YARWAY BOILER SKIMMER prevents the formation of scale by automatically and continuously removing impurities from the boiler feedwater. What it has done for this well-known concern, it can in all probability do for you, if you are having trouble with scale in your boilers. It will surely pay you to investigate, at least.

YARWAY

Boiler Skimmer

(A Continuous Circulating Surface Blow)



Description—Temperature difference between water in boiler and wate[r] circulation pipe 3 and settling chamber 5 causes constant circulatio[n] direction of arrows. Scum and foreign matter are constantly drawn fr[om] boiler and in passing slowly through settling chamber 5 sink to bottom [of] chamber 11, whence sediment is blown out through blow-off valve 12.

EVERY 7 DAYS A CARLOAD SAVED

ELESCO superheaters save fuel—In large plants a saving of 10 per cent. may be reasonably expected.

In a plant operating 24 hours a day, under a load of 5000 K.W., 2100 tons or 50 carloads of coal are saved a year by superheating. A carload is saved every 7 days.

In smaller plants, savings as high as 20 per cent. are disclosed. May we show you how the installation cost is quickly wiped out by the saving in fuel?

Voorhees Rub-Steel Valves

THE SUPERHOT GRADE

for high temperature work such as: Boiler Feeds, Locomotive Boiler Washing, Condensing Against High Heat and Oily Matter, Oil Refinery Service, Vacuum Returns on Heating System. For mild acids, etc. This Valve will not buckle under quick interchange of the temperatures.

One installation will convince YOU.

Booklet on Request

HEPBURN PUMPS

For Marine and Land Service

This is the Hepburn "Special" Outside Packed Ram Pump, designed for high steam pressure and for water of high temperature. It has only one packing gland to need attention and no bucket rings to change. This Pump is more efficient than piston pumps and upkeep charges are less. The valve motion is extremely simple and positive in action. No loose parts to need attention and no adjustments necessary.

Write for Catalogue.

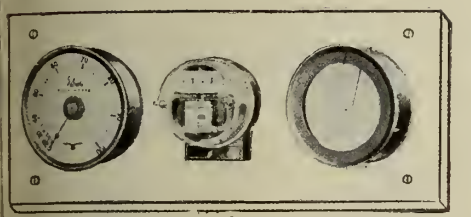
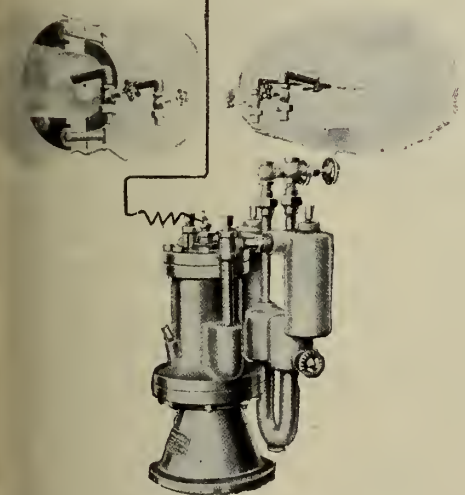
Republic Flow Meters



Meters that Show Where Your Dollars Go

Illustration of part of the Republic System showing the three reading instruments at the top: Indicating, Integrating and Recording.



Point Out the Waste In Power Transmission

THERE must be waste; there is bound to be wasted fuel in that power plant that has no means of knowing the amount of steam produced each day in proportion to coal consumed.

With coal so high in price the cost of producing steam should be carefully checked for it represents an item of expense on a par with labour and material.

Thoughtful manufacturers find that Republic Flow Meters practically eliminate all power waste by delivering accurate, dependable records showing clearly the steaming performance of each individual boiler—records that are as valuable to the engineer as accounting records to the manager.

Republic Flow Meters have actually increased the capacity of a boiler more than 12% with the same amount of coal. This because the operator can instantly tell which boiler is not producing or when grates need cleaning, scale cleaned from the boilers or other faults corrected.

In view of present conditions you need a Republic now more than ever. Besides measuring steam Republic Flow Meters will measure Water, Air and Gas. They give you dependable records—accurate to the minutest detail, whether the reading instruments are located near the meter body or at a great distance away.

This accuracy is constant, due to the fact that Republic Flow Meters operate by electricity. And this electrical operation means great flexibility and a ready conformation to every plant condition.

Write for complete explanation of the benefits of Republic Flow Measurement.

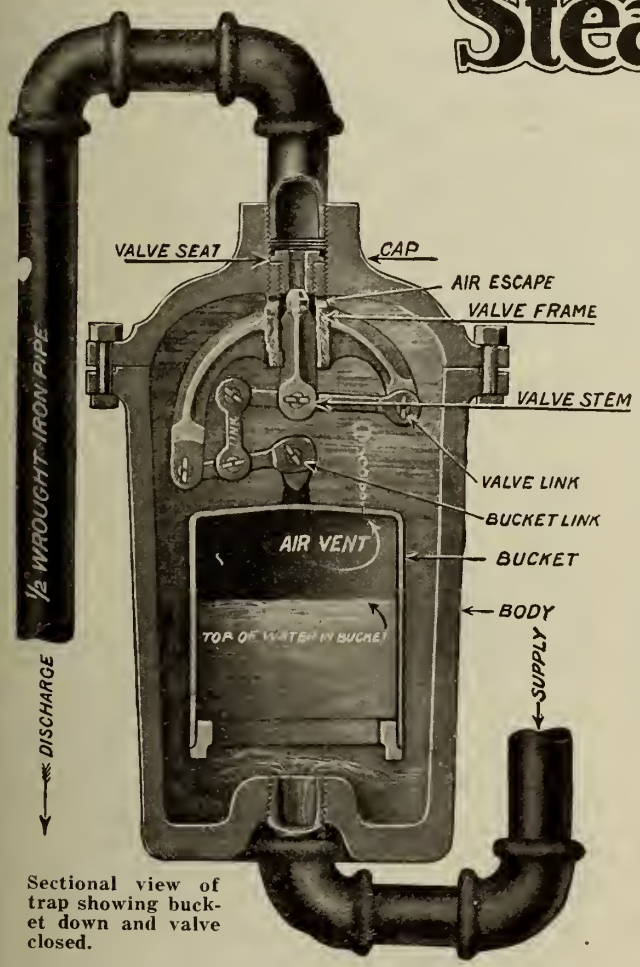
Armstrong Steam Trap



Sectional view of trap showing bucket down and valve closed.

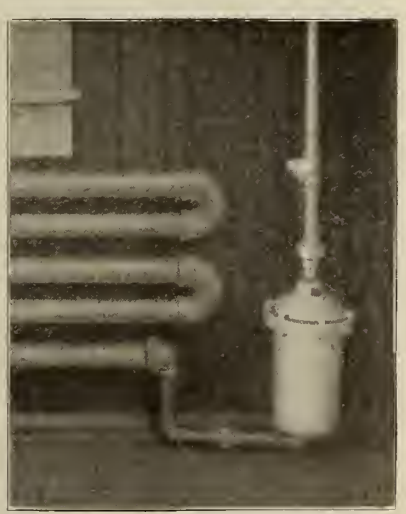
The Best Trap to Handle Condensation— Its Principle is Different

THE exclusive "Inverted Submerged Bucket" feature of the Armstrong Steam Trap mark it pre-eminently as the **best** trap to handle your condensation.

It absolutely will not pass steam. It will not become air-bound and is least affected by sediment, scale or oil. It requires a minimum of attention and upkeep; is compact, easily installed, and is of ample capacity for the work. Furthermore, it is an economical investment, cost, capacity and upkeep considered.

THE Armstrong Trap is small in size and light in weight compared with the ordinary trap. It is easily connected and may be suspended on a pipe line; neither foundations nor pits are required. This and the fact that an Armstrong is self cleaning and operates with little attention, is the reason for its widespread popularity with big power plants.

Write for details of our guarantee and 60-day offer.



A No. 2 Armstrong Trap draining a low pressure coil in Fairbanks-Morse & Co.'s plant. Note the water seal at the trap. Holes in the floor are unnecessary as Armstrong Traps need not be set below the coil.

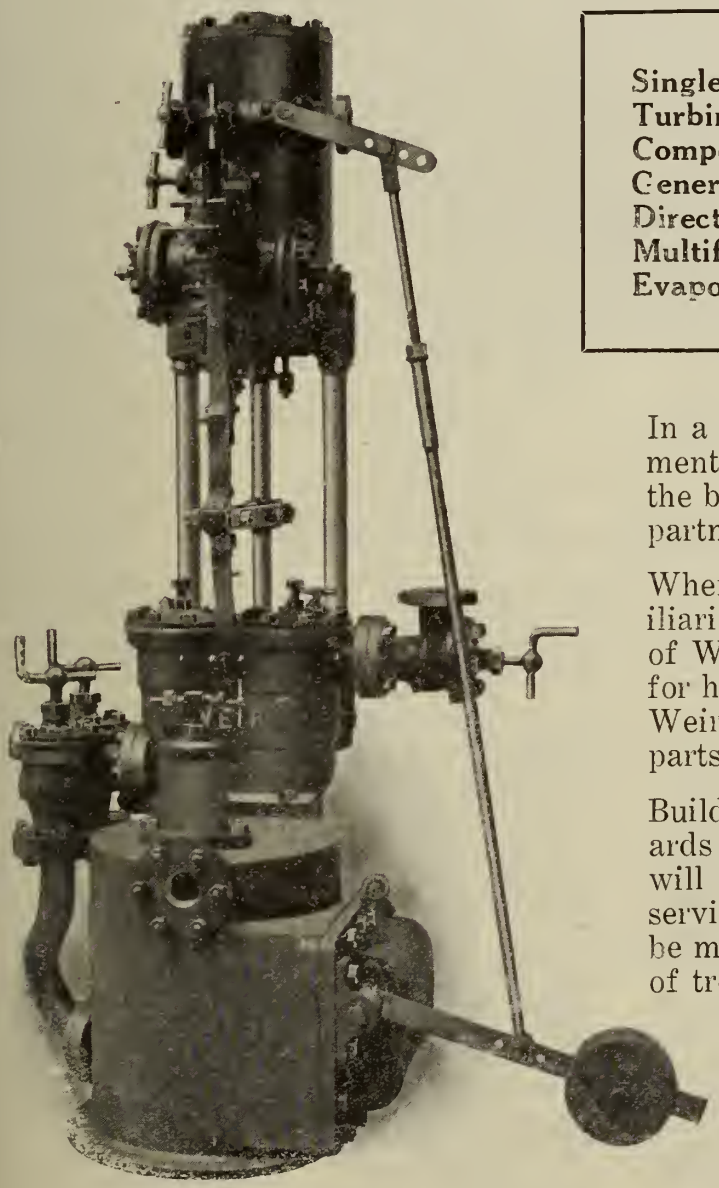
WEIR PRODUCTS



Single Acting Simplex Feed Pumps
Turbine Rotary Feed Pumps
Compound Feed Pumps
General Service Pumps
Direct Contact Heaters
Multiflow Heaters
Evaporators and Distillers.

In a power plant, dependable equipment is probably more necessary in the boiler room than in any other department.

When installing power plant auxiliaries consider carefully the merit of Weir Products—their reputation for high quality, and the well-known Weir system of interchangeable parts.

Building the parts to absolute standards insures that all Weir Products will give the same highly efficient service, and also enables repairs to be made promptly—with a minimum of trouble.

To all our customers we offer the entire resources of our organization—research, designing, manufacturing, operating—this is the Weir idea of service.

De Laval Turbo Generators in All Sizes

SMALL GENERATORS directly connected to the turbine constitute the simplest, most reliable unit for excitation, night lighting, etc.

BY THE USE of the De Laval Double-helical Speed-reducing Gear larger generators can be operated at standard speeds, while the turbine runs at high speed, insuring reliability and efficiency.

THE DE LAVAL Double-helical Gear, as perfected by 25 years of use in all services, is standard for use with steam turbines.

OUR EXPERIENCE in the design of turbine drives has been exceptionally wide. De Laval turbines are made for all steam conditions and for driving all kinds of slow, medium and high speed machinery. A statement of your steam and power conditions will bring the advice and suggestions of our Engineering Department.

TRADE PENBERTHY MARK.

BE SURE THIS NAME IS ON THE VALVE YOU BUY

CUT No. 544
Exterior View

CUT No. 544A
Sectional Side View

Get Away From Check Valve Troubles

by installing the

Penberthy Double Plug Check Valve

ON YOUR STEAM LINES

"Government Approved for 200 Lbs. Steam Pressure"

The double plug construction makes it possible to take the valve apart if mounted on a wall pipe without disconnecting same from the pipe. The plugs also act as bearings for the disc carrier pin and in case of wear it is only necessary to renew either plugs or pin, making valve as good as new. The top plug "A" is also removable for insertion of screwdriver when regrinding disc and seat is necessary.

Cut No. 544A shows sectional side view and illustrates to advantage the liberal thickness of metal in diaphragm. (See letter D), also the even distribution of metal throughout. The disc (letter E) is also of liberal thickness, and as same is made of a special wear-resistant bronze composition the Penberthy Check is practically indestructible and will give many years of efficient service. All genuine Penberthy Checks bear our trade mark and the registered pressure (200 lbs.) is also cast on each.

Highly Recommended by Leading Engineers

MANUFACTURED BY

Penberthy Injector Co., Limited - Windsor, Ont.

Let a Mason Engineer Get at the Root of that Power Loss

TRANSLATED into dollars and cents, are you getting full value from the coal that is costing so much to-day? Inefficient reducing valves mean wasted steam, and wasted steam means wasted dollars. In matters such as this, guesswork has no place. The one safe, sure and economical way to find out is to call in a Mason engineer—an expert who will quickly detect any leak and propose a remedy.

Mason Balanced Valve

Mason Service and Mason Appliances are to-day the first choice of thousands of power users. No other devices work so accurately, wear so long, or accomplish their purposes so fully as the Mason; and in critical positions they never fail. Appliances for pressure regulation, engine or pump control, damper or blower regulation and condensation drainage or returns.

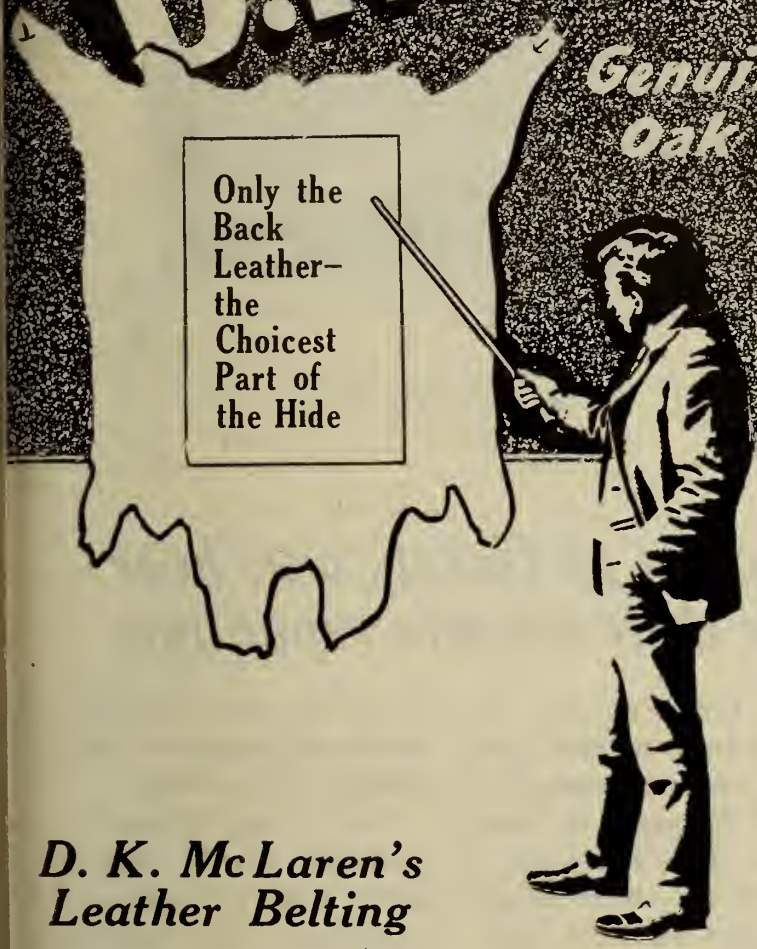
D.K.McLaren's

Genuine British Oak Tanned

LEATHER BELTING



D. K. McLaren's Leather Belting

is made from the BACKS of selected hides, skillfully tanned by the British Oak process. Every belt is just as good as we can make it.

Don't waste by belt slippage what you save by economical firing—else you are no farther ahead than the man who "guesses" the results he is securing in his power generation, and yet uses good belting to transmit the power he does get.

A leather belt will transmit 25 per cent. more power than the same sized belt of other material—therein lies the "economy of leather belting."

D. K. McLaren's Genuine British Oak Tanned Leather Belting reduces belt slippage and replacement to a minimum. Every inch can be relied upon to give satisfactory service.

The inside construction of Giants will bear as close scrutiny as their outside reputation

USERS have learned from actual experience that Giant Semi-Diesel Oil Engines stand alone on the basis of *dependability* and operating economy.

And the attendants of these engines have learned that Giants, due to their rugged simplicity, are practically independent of the human factor.

Giant Oil Engines are preferred because they possess the greatest number of *advanced* features of construction. This statement is confirmed by their inside construction features illustrated above.

Each feature shown does a *necessary* job in delivering power at lowest possible costs, contributing to an indefinitely long service life, every-day dependability, and operating simplicity that lessens attendant costs.

On a basis of year-in and year-out worth, fuel economy, lowered upkeep and attendant costs—how much can Giants save in *your* plant? How soon could a Giant pay for itself? If you wish, a C-P sales engineer will help you find out.

Dependable Power at Less Cost Per Hour

Proper Lubrication Pays

TROUBLE with plant machinery usually simmers right down to a problem of correct lubrication. Hasn't that been your experience time and again?

The *right* lubricating oil for every working part is your best insurance of smooth running, effective mechanical units—which, in turn, means full-capacity plant operation.

Engineers who have standardized on Imperial Lubricants find the quality uniform with a grade especially suited for every type of machine. And *immediate* supplies are always available in any quantity.

Imperial Lubrication Engineers co-operate with plant engineers and superintendents to get more work out of power-producing and power-using equipment at lower lubrication costs. An experienced Imperial Oil man will gladly make recommendations for the particular needs of your plant.

You'll Know It By The Diamond Trade Mark

Dependable performance is guaranteed the buyer of Diamond Trade Marked Valves.

The name "Jenkins" within a Diamond Mark cast on the valve body—every **genuine** Jenkins valve carries it, a protection to the customer against inferior imitations.

And whatever the service, whether for steam, water, oil, air, gas or chemicals, genuine Jenkins Valves will prove safe and dependable.

Jenkins Valves are made to serve. They are designed throughout for the **maximum** service, not merely the average—and tested in this regard before leaving the factory.

Supply houses everywhere carry a complete stock of Jenkins Diamond Trade Marked Valves. Catalog No. 8 (free on request) will show you how comprehensive the Jenkins line is—a valve for every purpose.

No Furnace Repairs Needed

That's what the engineer says whose furnace is lined with

PLIBRICO JOINTLESS FURNACE LINING

PLIBRICO makes a solid, one-piece lining without joints. By its use your boiler is brought to the highest point of efficiency, for, being jointless, the lining is absolutely air-proof and gas-tight.

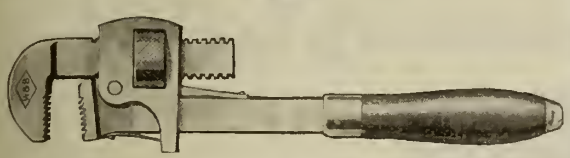
Any laborer can install PLIBRICO—if he can use a trowel and a mallet. No special forms are required.

PLIBRICO can be installed in any kind of furnace. It is also ideal for repairing old broken-down linings, filling in cracks or holes, or replacing missing bricks.

Shipped in steel containers of distinctive appearance as shown below. Warehouse stocks carried in all principal cities for immediate delivery.

Stocks carried in Montreal, Toronto, Winnipeg, Vancouver and Calgary.

Write for book on Furnace Building.



Williams' Stillson Wrenches

Are sturdy and dependable—well balanced—positive in grip—powerful in action.

The tough teeth retain their sharpness; they "bite" instantly, yet release readily.

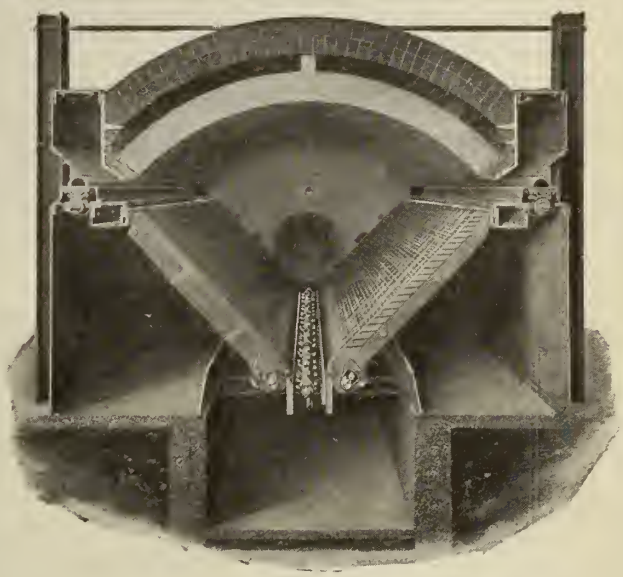
MURPHY AUTOMATIC FURNACES



Spending to Save

To-day you are vitally interested in reducing production costs. Is your power plant one of the many using hand-firing methods for boilers from 50 H.P. up to 300 or 400 H.P.? If so, you have an opportunity you cannot afford to overlook.

Investigate Murphy Automatic Furnaces and you will learn how thousands of satisfied users all over the country have made a saving of 15 to 30 per cent. on their coal bill—at the same time eliminating black smoke.

Spending money now to save money by reduced costs is not extravagance—it is sound, common sense.

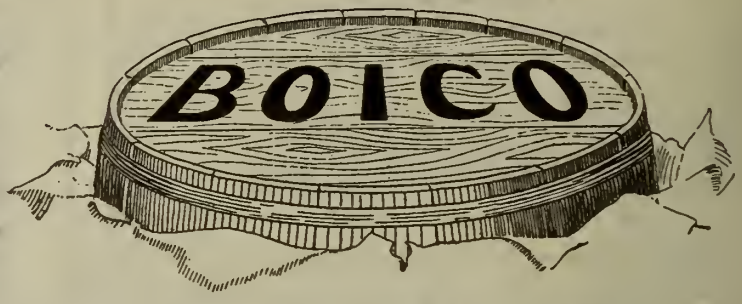
Murphy Furnaces can be installed under any type of boiler from 50 H.P. up. Ask us to send you our Catalog HM-3.

For information on RILEY UNDERFEED STOKERS for large boilers, see last month's advertisement or send for RILEY STOKER Catalogue HR-3.

MURPHY IRON WORKS
DETROIT MICH. U. S. A.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.



Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. **Maximum** air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

There's a Tycos or Taylor Temperature Instrument for every purpose

Ten hours! More than a day's labor! Think of the cost in dollars!

Such was the result of a test between the flexible type of hack saw and an all-hard blade,

Both were designed to cut the same material! Both were carefully run to deliver the utmost service, but the all-hard blade demonstrated from the start that it cut costs by cutting quicker. On power sawing, where weight is needed to make the teeth of a blade "bite" into the stock, the soft-back saw is not practical. Because of its flexibility, pressure makes it "buckle" Without this weight the cost per cut is too high.

For economical power sawing the proper blade for the particular kind of material to be cut is indicated by the Starrett Hacksaw Chart. It will be mailed to you, free.

Cut Your Oil Bills in Half!

THE ANDERSON PRESSURE OIL FILTER

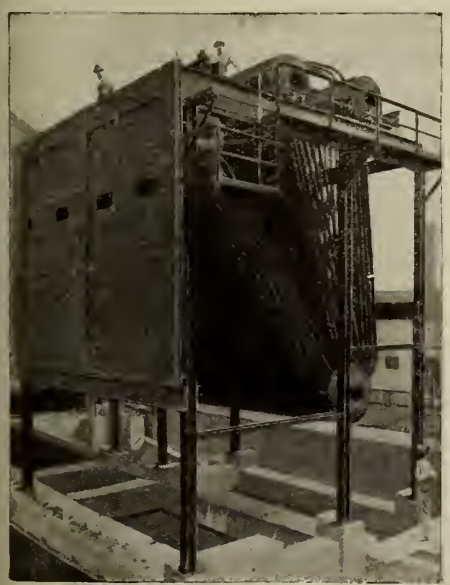
will save practically all the oil that is now wasted on wipers. As almost fifty per cent. of the oil used is wasted in this manner, think of the saving an **Anderson** means to you.

By placing drip-pans beneath the machinery and passing the collected oil through an Anderson Pressure Oil Filter, clean, pure oil may be obtained—oil that is identical to that of the refiners. And this operation can be performed over and over again.

In a few months the Anderson will save enough oil to pay for itself. You can't afford to be without this money saver.

Write us about it now

The V. D. Anderson Co.
West 96th Street, Cleveland, Ohio



Connelly Water Tube Boilers (*Patented U.S. & Canada*)

are of the 4-drum type; have 100% tube area in the path of circulation, and deliver steam superheated to from 5 degrees to 10 degrees Fahrenheit. Simple in design, no flat surfaces, no stay bolts, no crown bars, no braces, no handholes, free from joints.

All parts easily accessible for cleaning, both internally and externally. Can be built in units from 200 H.P. up to 4,000 H.P. and 300 lbs. pressure. 150,000 H.P. in successful operation.

Good Times Just Ahead

PROSPERITY is within our reach in Canada.

--All we need to have and to hold it is a sane, sure grasp on its simple elements.

They are Industry, Integrity, and Faith.

These are the cardinal virtues of human relations. They are the underpinnings of healthy, natural business life and the foundation of a wholesome social system.

They are the fountainhead from which Progress springs. A well-known business economist has called them the "Fundamentals of Prosperity."

Your purchases are an expression of Faith. They are evidence of your Industry. Make them confidently from business institutions of Integrity.

Buying is the backbone of prosperity. An active market means more employment, steadier earnings; benefits are passed around.

Wise spending gives stability to earning and for that reason is far-sighted thrift and sound economy.

The call of to-day is for cheerful thinking, willing working and constructive action by you—everybody—NOW.

To-morrow's change for the better will come about through the combined efforts of each and every one of us.

By sheer force of numbers and co-operation, by the high power of heart and mind, we can put Business on a firm, stable basis.

We can do this because all of the material factors making for better business are right.

Let us link our faith with industry, our vision with courage, and forge ahead.

Let's make an uncommon effort toward a common end—Good Times.

A message from the Associated Advertising Clubs of the World.

The Jones Under-Feed Stoker in operation

The JONES

Jones Stokers
for plants of every type and size

Jones "A-C"
Automatic - Cleaning — Automatically - Controlled

JONES "A-C" Stokers are high-duty stokers. In many large plants from coast to coast they are operating continuously at heavy overloads. The automatic-cleaning ("A-C") feature saves labor. No hand cleaning is necessary. Clinkers are not formed on furnace walls. Fuel and air are automatically supplied in the right proportion for complete combustion with highest economy. Fires are automatically kept in perfect condition. Coal consumption is materially reduced.

Write for a complete "A-C" Catalog.

Jones "Standard"

JONES "Standard" Stokers are suitable for smaller plants. They can be installed under any boilers without disturbing boiler setting. No excavations are necessary. Like the "A-C" type, they are extremely simple in design and operation. Few moving parts—none in the fire. Foreign matter in fuel cannot cause damage. No shearing pins used. Very low maintenance cost. Smoke is prevented. Automatic fuel and air regulation insures best possible economy without expert supervision.

Write for a copy of the "Standard" Catalog.

Type B with Superheater

Goldie & McCulloch Water Tube Boilers are equipped with large steam and water drums and connecting nipples of increased size, thus providing greater combustion area and increased steaming capacity. These important features of the design and construction of G. & McC. Water Tube Boilers give them a great advantage over ordinary boilers. Every part subjected to steam pressure is made of **forged steel. They can be forced without danger.**

Let us tell you their other points of superiority. Write to-day for Catalogues, etc.

Principles of Series and Compound Motors

Torque of a Series Motor—Speed of Series Motor—Comparison of Characteristics of Series and Shunt Motors—Compound Wound Direct-Current Motors—Differential Compound Wound Motor

By TERRELL CROFT. Copyright. All Rights Reserved.

THE series motor is shown diagrammatically in Fig. 1. It consists merely of an armature and series field winding connected in series and almost invariably operated from a constant e.m.f. source and a constant impressed e.m.f. is assumed in the following discussion. Obviously, the current in the armature and in the field winding must, at any given instant, be the same.

The characteristics of the series motor are shown graphically in Fig. 2-II where they may be conveniently compared with those of the shunt motor of I.

The torque of a series motor, when the magnetic-circuit iron is being worked well below the saturation point, varies nearly as the square of the current. Thus, motors of this type have splendid starting torque. Torque varies as the product of flux, ΦP, and armature current I A. Now in a series motor, if the current is doubled, the flux is also doubled (approximately), since the armature current traverses the field coils. Hence, the torque (proportional to: current x flux) is increased four times. When the load being driven by a series motor increases, the motor slows down, hence its counter e.m.f. decreases. Then its current increases and its torque increases as the square of the current tending to assist the motor in pulling the load.

The speed of a series motor varies (Fig. 2-II) with the load. For any given h.p. load which a certain series motor is driving, there will be a certain definite speed. With a heavy load, a series motor will operate at slow (relatively) speed. With a light load it will operate at a high speed. With no load it will, theoretically, operate at an infinite speed, that is, it will "run away." The explanation of this is:

Any armature always tends to operate at such a speed that the sum of the volts lost in its armature, in I R A drop, and the volts counter e.m.f. induced will equal the impressed voltage. At heavy loads the current, and consequently the I R A drop in a series motor armature, will be

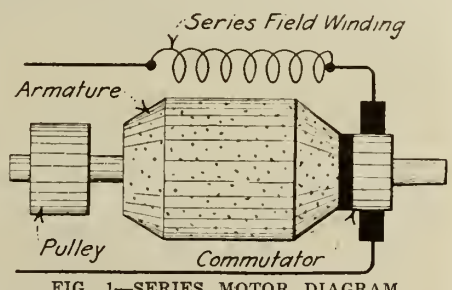

FIG. 1—SERIES MOTOR DIAGRAM

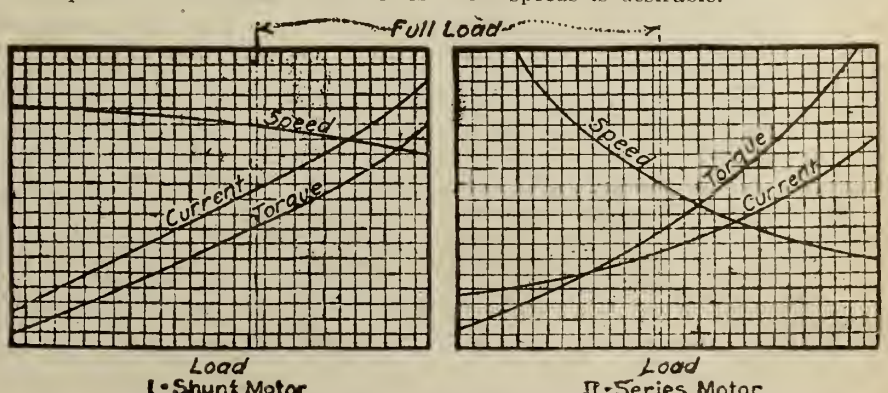
large and it is not necessary for the armature to rotate very rapidly to induce the required counter e.m.f. But suppose the load is thrown off the motor. There now being no resisting torque the motor speeds up, inducing a higher counter e.m.f. and decreasing the current through the field coil and armature. This weakens the field, causing a further increase in armature speed, which again decreases the counter e.m.f. With a series motor operating without load this process continues until the armature "bursts," due to great centrifugal stresses.

A comparison of the characteristics of series and shunt motors is given graphically in Fig. 2. Since in the shunt motor the field is practically constant, its torque varies directly with the current (approximately). As shown above the torque of a series motor varies almost as the square of the current. The series motor has, then, a much greater starting torque than has the shunt motor. Hence, a series motor of a given size, that is, weight, will start a much greater load than will a shunt motor of the same weight. The shunt motor has a practically constant speed for all loads within its capacity, while the series motor has a certain speed for each load—its speed varies with the load.

The applications for which the series motor is adapted are limited because of its speed and torque characteristics which are described above. The motor is not adapted to drive loads the power required by which varies, but which should be driven at a constant speed. The reason is that the speed of a series motor varies with the load. Hence, series motors are not, in general, adapted for machine tool or line shaft drives. If it were used for such, the speed would be low when the load driven was great and high when the driven load was light. Furthermore, since a series motor will "run away" at no load, it should be applied only where it can be geared or otherwise permanently connected to its load. Crane, hoist and railway traction application are good examples of services for which the series motor is well adapted. In other words, the series motor is fitted for conditions where constant speed is not necessary but where great torque at low speeds is desirable.



CHARACTERISTIC CURVES OF SHUNT AND SERIES MOTORS.

In starting series motors an adjustable resistance is connected in series with the motor across the source of impressed e.m.f. (Fig. 3) to prevent an excessive rush of current at the instant of starting while the armature is stationary and inducing no counter e.m.f. As the armature attains speed, the effective resistance of the rheostat may be decreased by turning the handle. The function of this starting resistance is the same as that of the armature resistance used in starting a shunt motor.

The speed control of series motors is effected by changing the resistance in circuit between the motor and the source of constant e.m.f. The same rheostat (Fig. 3) may be used for this as is used for starting the motor, providing its resisters have sufficient current-carrying capacity to prevent their overheating in speed-control service. The method is somewhat similar to armature speed control for shunt motors. It is subject to the same disadvantages. When the effective resistance of the rheostat is

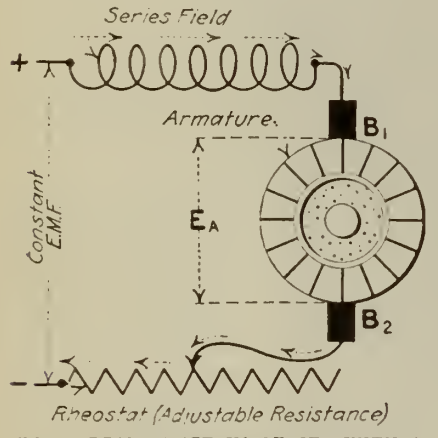


FIG. 3—RESISTANCE IN SERIES WITH A SERIES MOTOR.

varied, the voltage across the armature, E A, Fig. 3, is varied accordingly and the armature then "speeds up" or "slows down" correspondingly until its counter e.m.f. equals (approximately) the e.m.f., E A, impressed across the armature. Thus while it is true that a series motor has a definite speed when driving any given load with a given e.m.f. impressed across its armature, its speed when it is pulling a given load may be altered by changing the e.m.f. across the armature.

Series motors are extensively used for driving electric cars because their torque and speed characteristics render them especially fitted for this service. Shunt motors would not be well adapted for propelling a car as they would tend always to drive the car at about the same speed and on grades and in starting the motors would be greatly overloaded. Practically all of the cars in city service are driven by series direct-connected motors. Many of the cars and locomotives in suburban and trunk line service are also driven by direct-current series motors although alternating-current motors have recently been applied to some extent for this work. Cars are equipped with two or four motors so that the

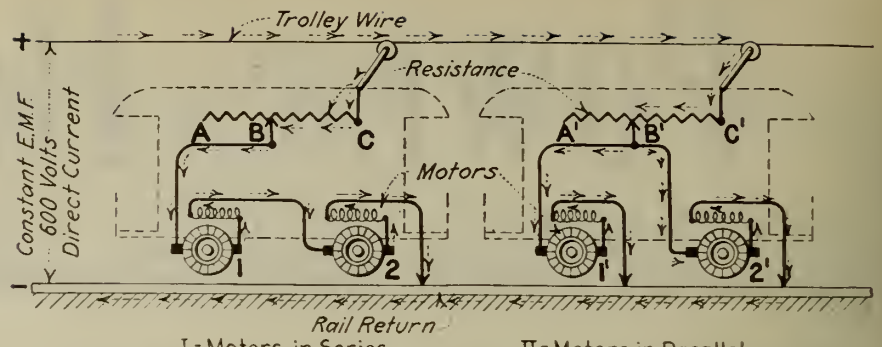

FIG. 4—SHOWING HOW TWO SERIES MOTORS DRIVING A STREET CAR ARE FIRST CONNECTED IN SERIES AND THEN IN PARALLEL.

torque may be applied at both trucks and so that series-parallel control (Fig. 4) may be used.

Series-parallel car control is used principally because it is economical. The controller located on the car platform and operated by the motorman is merely a rotary switch whereby the different series and parallel connections of the motors may be effected. Briefly, the operation is this:

Refer to Fig. 4. Advancing the controller handle to the first "notch" connects both motors, 1 and 2 (Fig. 4), in series with all the starting resistance A C in series also. As the controller handle is swung around the starting resistance is gradually cut out, meanwhile, until both of the motors are connected directly across the line without any intervening starting resistance. Throwing the controller around another notch connects the motors in parallel between trolley and rail but again in series with all of the starting resistance A'C'. As the car accelerates the controller handle is swung around until the motors are connected directly in parallel between trolley and rail.

The notches whereat the motors are connected without resistance: (1) in series between trolley and rail and (2) in parallel between trolley and rail—are termed running notches and are shown by longer raised marks on the controller top-casting than are the others. When the controller handle pointer is over either of these marks no power is being wasted in starting resistance—all power as taken from the line (except motor losses) is being expended by the motors in propelling the car.

Where the two motors are connected in series, only half the line current is required to start the car that would be necessary for starting with the motors in parallel. Assume that it takes 50 amp. through each motor to start the car. With the motors in parallel 100 amp. would flow from the line, but with the motors in series only 50 amp. flow from the line. With the motors in parallel resistance in series with them it would be necessary to limit the current through each to 50 amp. But with the motors in series each motor takes the place of a starting resistance for the other. Thus the economy of series-parallel control is obvious.

Compound-wound direct current motors partake of the characteristics of both shunt and series motors just as compound-wound generators partake of the characteristics of both series and shunt generators. Fig. 5 shows typical characteristic curves for a compound-wound motor. A compound-wound motor may be made to approximate more or less the characteristics of a shunt or a series motor respectively by making the amp. turns of its shunt or series windings more or less powerful proportionately. The elementary connections of a compound-wound motor are the same as those of Fig. 6 for a compound-wound generator.

A differential-compound motor has its windings connected as shown in Fig. 7-I. Its series-field winding "bucks" or opposes its shunt-field winding. A motor of this type can be arranged to operate at an almost exactly constant speed under varying load. As the load increases and the motor tends to "slow down" the series-field magnetization increases and

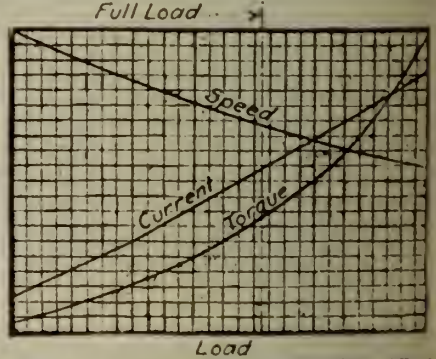

FIG. 5—CHARACTERISTIC CURVES OF A COMPOUND WOUND MOTOR.

since it opposes the shunt-field magnetization (which is normally greater than the series magnetization) the resultant field is weakened and the motor maintains the same speed as before. Of course the proportion of shunt-field turns and series field turns must be exactly correct if this result is to be attained. If the ratio of turns is such that the series turns are more powerful than the shunt turns, the motor will "speed up" under increased load. The speed regulation of a differential-compound motor may be closer than that of a shunt motor but its starting torque is not as great.

A cumulative compound motor is so connected that its series turns augmen

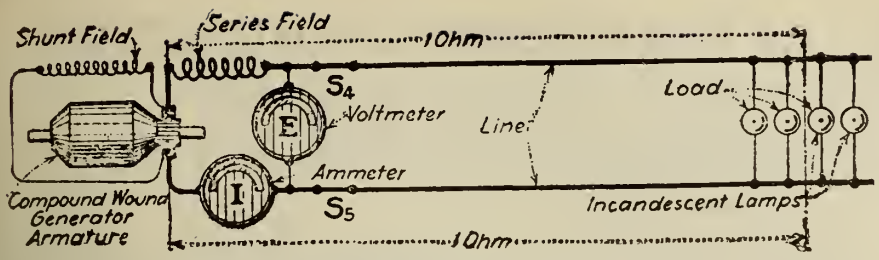

FIG. 6—COMPOUND WOUND GENERATOR SERVING LOAD, WITH INSTRUMENTS IN CIRCUIT FOR TAKING CHARACTERISTIC DATA.

the shunt-turns magnetization as shown in Fig. 7-II. A motor thus connected will have strong starting torque, stronger than that of a shunt motor, but its speed regulation will not be as good. Motors of this type are used for shears, rolls and similar applications where close speed regulation is not necessary but where great torque may be desirable at starting and while running. Frequently motors of this type are merely series machines provided with sufficient shunt turns to prevent the motor from "running away" when operating at no load.

The starting and control of compound

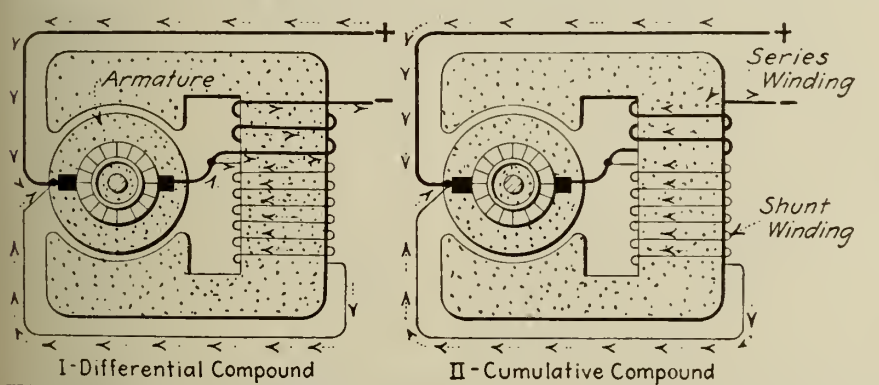

FIG. 7—DIAGRAMS OF DIFFERENTIAL AND CUMULATIVE COMPOUND WOUND MOTORS.

motors is, in general, similar to that for shunt motors. The same starting rheostats can be used for ordinary compound as for shunt motors. Ordinarily the series winding has no special connection to the starting rheostat. Sometimes provision is made whereby the series winding may be shunted out of circuit after the motor has been started. The possible special-control arrangements are too numerous to enumerate.

TIDAL PLANT AT SEVERN RIVER

More details of the 500,000 horsepower tidal-hydro-electric scheme, fathered by the British Ministry of Transport and first reported by cable several weeks ago, are contained in a recent issue of the London Electrician. This ambitious plan, which aims at the production of 500,000 horsepower in a ten-hour day, with a peak load of 1,000,000 horsepower, at an estimated cost of a little more than 1 cent per kilowatt-hour, is based on the construction of a dam across the Severn River and the utilization of the tidal power. With the project are linked in plans for an extensive highway and railway development and for a locked basin for shipping purposes, 27 square miles in extent, a very large portion of which would, it is held, be suitable for the accommodation of vessels of the largest size and which would be usable at all stages of the tide.

There would be two separate installations required, a great concrete dam across the Severn, within which sluices and turbines would be installed for utilizing the power of the tides and with which would be combined a road bridge and a railway bridge, and a high-level storage lake and tunnel with a pumping and turbine house on the banks of the tidal portion of the Wye River, which empties into the Severn. It is proposed that water be forced up from the low level of the Wye through a 40-foot tunnel driven through more than a mile of solid rock. The sea water would be pumped into high-level reservoirs during the rising tide, and this stored water would be used to supply the turbines at ebbing tide. The site which has been selected for the barrage lies close to the line of the existing railway tunnel between South England and South Wales at a place where the estuary is about 2½ miles wide with low-lying country on each side.

It is held that the power available on the Severn exceeds all the other potential sources of inland water power within the United Kingdom and is also unique in combining all the conditions essential to the economic development of tidal water power on a large scale. These conditions present an exceptionally high range of tide, an estuary of large capacity, an ideal geographical situation in relation to the industrial centers of the country, and suitable land along the banks of the river for the development of industrial operations. The capital cost of the scheme is not explicitly stated, but the Electrician understands that £30,000,000 is about the figure, exclusive of expenditure for transmission lines.

C. A. S. E. HAMILTON

Monday, March 7, the C.A.S.E. No. 2 held an open meeting at which a lecture and slides on the Green Economiser was given and much enjoyed by all, some of the men present having worked for the Green Economiser people in England. We appreciate the kindness of that company in sending the slides through Executive Secretary Brother L. J. Ellis.

It is the intention of the officers of the lodge to have an open meeting the first meeting night of each month.

INTERESTING TURBINE INSTALLATION

An interesting feature of turbine operation is recorded in the installation of a 55 horsepower De Laval turbine in a herring drifter. The turbine is geared down to operate twin screws, and is used to help the sail as well as for propulsion when there is no wind. The interesting feature from the engineering point of view is that owing to the fact that the quantity of steam passing the nozzles did not vary to any appreciable extent with variations in the velocity of the turbine, but only with the steam pressure, the turbine became much more efficient with higher speeds. This occurred when the vessel was sailing, the turbine revolving much faster owing to the decreased resistance, and the combined speed with sail and steam was about equal to the sum of the speeds achieved with either motive power separately.

BURNING FUEL OIL

Set the burners open wide,
Do not touch the valves at side;
Keep the pressure on the pump,
And up the bally steam will jump;
If the smoke is black and thick,
Open up the fans a bit;
If the smoke is thick and white,
To slow the fans will be quite right;
For when sufficient air is given,
No smoke ascendeth up to heaven.
If the jets refuse to squirt,
Assume the cause is due to dirt.
Should the flame be short and white,
You have combustion clear and bright;
But should the flame be yellow and long,
Combustion is entirely wrong.
A wise man to his heater sees,
And keeps it 200 degrees;
To have it more is not quite wise,
Because the oil may carbonize;
A little lower has been found
To give as good results all round.
If the filters are kept clean,
No rise in pressure will be seen;
But should the pump kick up a ruction,
There's likely air within the suction.
The pressure governs the supply,
So do not keep it very high.
If these instructions you will follow,
You'll beat the other fellow hollow.

Changing of Lap to Butt Seam Construction

Effect of the Unequal Rolling of Plate Edges in Lap Joint Construction—The A.S.M.E Code Regulation as to Age of Boilers With Lap-Jointed Longitudinal Seams—Lap Seam Cracks Seam Cracks

NOT long after the steam boiler came into general use in America considerable discussion was aroused with respect to the question of limiting the life of a boiler, says the Locomotive. Numerous instances of serious accident, which it seemed impossible to account for, had impressed many with the idea that a boiler, like any other piece of apparatus, was subject to deterioration from constant use and that therefore it would be best to take a boiler out of service after a certain period. In fact, a number of concerns followed this practice. The majority of boiler users and engineers, however, felt then as they do now that rigid inspection would safeguard their boiler plants and would furthermore be of greater service in the interest of economy, for it was admitted that many boilers had served for twice the life that, by some, had been allowed for safety.

The plan of relying on inspection for a forewarning was adopted and served well, but there were a number of unaccountable explosions in boilers of relatively short life. At the time, the majority of boilers in use were constructed with a longitudinal lap joint. A series of investigations was conducted to study the stress conditions in this type of joint and it was found that the construction, both from its fundamental shape and the conditions of manufacture, presented a most dangerous condition.

In the Locomotive for April, 1905, there appeared an account of the disastrous boiler explosion at Brockton, Mass., on March 20, 1905, and also an article on the "Lap Joint Crack" to which type of defect the explosion was said to be due. For the sake of clearness we shall present here some of the more important points which were brought out in the last named article.

When a boiler plate is rolled to a cylindrical form, the edges of the plate, in passing through the rolls, are not gripped as effectively as is the middle of the plate, so that the ends are left somewhat flat. The condition produced is illustrated in Fig. 1. This necessitates the plates being forced together at the edges and this produces an added stress that persists unless relieved by annealing. In addition to this the plates, if bent after punching, will bend along a line of rivet holes as shown in Fig. 2 in somewhat exaggerated form.

The elementary lap joint is illustrated in Fig. 3. If tension is applied as indicated in Fig. 4, the plates, in an attempt to align themselves with the load, will

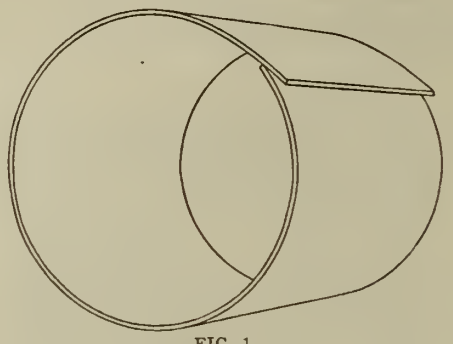

FIG. 1.

bend along a line running under the outer edge of the rivet heads.

The combined effect of all these conditions, together with the constant bending of these joints by changes of pressure when in use, is to impose excessive stresses in the surface of the boiler plate along the line just mentioned. This has produced, in many boilers, a crack which starts always from the inside or covered surface of the inside or the outside plate of the joint as indicated at A and B in Fig. 4. This crack may eventually work its way through the plate until it shows itself by breakage. But in many cases it may develop for some distance along the joint and yet remain absolutely invisible. Eventually the weakness may develop to the point of complete failure and a disastrous explosion.

Inspection is generally accepted as being safe for the determination of the fitness of a boiler for use. The lap seam crack, however, is invisible to all methods of inspection, except cutting out the rivets and separating the plates or the method described in the Locomotive for October, 1914. Recognizing the insidious danger presented in the lap joint for longitudinal seams in boilers, the Boiler Code Committee of the American Society of Mechanical Engineers formulated the following regulation: (Par. 380, A.S.M.E. Boiler Code, Edition, 1918.)

"The age limit of a horizontal return-tubular boiler having a longitudinal lap joint and carrying over 50 lbs. pressure shall be 20 years, except that no lap joint boiler shall be discontinued from service solely on account of age until 5 years after these rules become effective."

Some boiler owners may be of the opinion that the longitudinal lap seams of boilers of this type can be changed to butt strap construction and the boilers kept in service after the time limit. This change of design and construction is not approved, however, by those thoroughly familiar with steam boilers, for, although butt straps and more rivets may be added, the material along the line of the joint, which was abused and tortured by the forming of the lap joint and fatigued by the years of service which subjected it to the expansion and contraction brought about by the many changes of temperature and pressure, would be further abused on the portion of the original construction left after cutting off one side of the lap joint and forcing the edges of the plate into line to form a butt joint.

Assuming that a double riveted lap joint has been changed to a triple riveted butt construction, the joint, after placing the butt straps and riveting, would appear as shown in Fig. 5 on page 145 with the rivet holes of the original lap joint at B and the new holes at C. If a defect existed in the plate as shown at A the joint would be very faulty. Assuming the original joint as having the rivet holes spaced 3¾ inches and the additional holes spaced 6½ inches, if the plate material were defective or contained a lap crack as shown, the failure of the joint would require only the shearing of the rivets in long pitch, or 6½ inches, and the failure of the defective plate.

It might be argued that the exposure of the inside of the lap seam, when the change to a butt seam is made, would reveal the presence of a lap seam crack. A crack of this nature is, however, often present in a boiler of this construction after years of service, although it may not be visible to the naked eye. But,

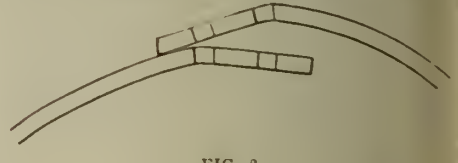

FIG. 2.

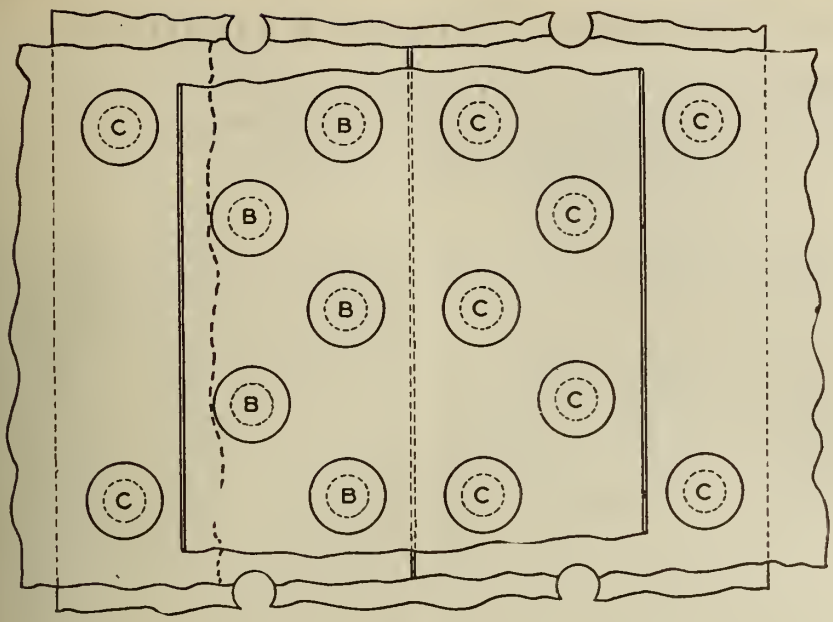
even though no crack exists, it must be remembered that boiler plate, like any other material, becomes fatigued after long years of service and for this reason, after it has been under stress for many years, it should not be subjected to a change of shape and torture of the material in an endeavor to keep the boiler in service, especially when there is evidence that the altered structure is defective.

The age limit of twenty years is none too exacting as will be evidenced by an explosion, resulting from a lap seam crack, of a boiler at the Tallahoma Lumber Co., at Mossville, Miss., on October 21st, 1920. This boiler was less than five years old. The explosion completely



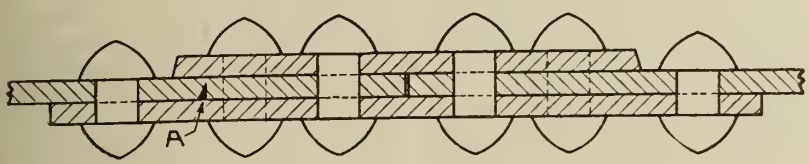


FIG. 5.

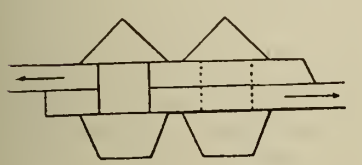

FIG. 3.

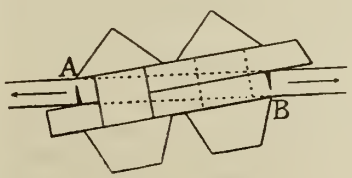

FIG 4.

wrecked the plant, killed three men and injured four others. There was no negligence on the part of the operators and there was ample proof that the accident did not result from low water or overheating. On the other hand, the lap seam cracks could be clearly seen in the boiler plates after the disaster.

Regulations such as we have quoted are not intended to be arbitrary. Railroad companies determine the safe load capacity for each of their freight cars and if they discover an overloaded car they refuse to transport it. This is done not only to avoid the possibility of straining or breaking the overloaded car, but also to prevent a possible wreck which might result in loss of life, property damage, and delay. In a like manner the Boiler Code Committee requests that steam boilers and pressure vessels be designed and constructed for a safe working pressure and that they be not subjected to overloads. The rule quoted above is sane and economic because it is intended for the protection of life, limb and property. So also should be regarded the action of the boiler inspector in condemning any construction regarded as unsafe.

STRAIGHTENING A ROTOR SHAFT

By D. A. HAMPSON

The method of straightening a rotor shaft described in the January 20 issue is both novel and instructive; it is one that should suggest a way out of other ticklish straightening jobs. There is no question but that there are unrelieved stresses in a shaft so repaired—if there is a suitable factor of strength in the original shaft and if the service is not fatiguing, no harm will result. The conditions under which a repair is performed often make it necessary to violate the teachings of theory, but if results are the true test of engineering, then such repairs must constitute good practice.

Some time ago a screw was brought into our place to be straightened. It was a piece of steel twenty feet long over all with fifteen feet of square thread, single, having a pitch of one inch and an O.D. of three. This screw was part of a special machine and moved a heavy carriage back and forth. Something had blocked the carriage and the screw, making 200 r.p.m., had bent close up to the nut. It was a job we did not want to do for obvious reasons, and we frankly told the customer so, but he did not want to send it away to the people who made the machines and he agreed to pay well for the time and accept all risk.

There was no lathe within forty miles that would take the length or over half of it, but we had a planer with a fifteen foot table, and by placing the screw diagonally (to dodge the slots), we were able to roll it on the top for sighting purposes. It was not hard to pick out the bend—a straight-edge would do that—but it is always of great assistance to rotate a piece being straightened.

Actual straightening was done by putting the bend down, with a block under this part to raise it half an inch from the table, and then drawing down on clamps on each side of the spot. The planer was a heavy one and we had no fear as to which piece would go first. Our fear was that we would get too far, and, worse, would get a reverse bend alongside the original one. To be safe, we bored out a piece of cast iron to three inches, and sawed it up into three pieces, putting a short section under the screw and longer ones under the clamps.

A swaging tool was also forged out and fitted to the space and curve between the threads. This was used to force back the metal where it had been compressed, thus assisting the clamps as pulled down, and putting a stress of compression in the metal where there would otherwise have been only the tension due to drawing the screw back to a straight line. As the clamps were pulled down, this swaging, or peening, was carried on—greatest at the point of bend and tapering off in amount for a couple of threads each side.

After a cautious trial of this scheme, followed by more confident repetitions, we pronounced the screw commercially straight. Indeed, it was a first-class job and surprised us ourselves. There was a certain amount of stretch at the critical point, that we knew, but as it was not discernible with a rule and showed up only when calipers were applied, we thought there would be no interference in passing through the nut—and luckily there was none.

WASTE OF NATURAL RESOURCES

As an example of how natural resources are thrown away, the following is reported in the Mexican press. The oil coming from the subsoil in the oil well district is mixed with a certain quantity of natural gas. This is separated from the oil before the latter is sent through the pipe lines, and the gas is then taken a considerable distance from the oil fields and burned. An investigation by the Department of Industry showed that three wells alone were producing and wasting in this way 1,200,000 cubic meters of gas per day. From this gas it would be possible to extract something like 60,000,000 litres of spirit per year.

Features of the Unaflow Steam Engine

History of Development—Cylinder Condensation—Unaflow Construction—Unaflow Engine Economy—The Flat Economy Curve Shown by This Type of Engine Under All Loads

By ROBERT CRAMER

NOT being connected with any manufacturer of unaflow engines, I am not an advocate of this engine in the usual sense of the word. My interest in the unaflow engine comes from the fact that from the very inception of this type of engine, I have helped to develop it; and I therefore believe that I am in a position to give you facts and information which will be interesting. The gentleman who spoke before me said that in no case was it a wise thing to say or even possible to say offhand that one engine, one type or another type, is just the suitable thing. That is true. You will have to investigate conditions in order to decide that question. Each type of engine has its merits. An oil engine drive has its merit in given cases and the electric drive has its merits and so has the steam engine.

It has been predicted for a long time and through many years that the steam engine will ultimately be driven from the field. First it was the steam turbine. Then it was the internal combustion engine and it is a remarkable fact that whenever another prime mover has gained a start on the steam engine that the steam engine usually has followed to a certain extent. In other words, it has reclaimed part of the field which had been taken from it. That is the case with the unaflow engine. The remarkable thing about the unaflow engine is that in small units, units down to as small as 50 horsepower, it can show the same steam economy as the largest steam turbines.

Electric drive in the majority of instances is derived from steam. If the very economical oil engine has difficulties in competing with electric drive in many instances, why doesn't the same thing hold good with the unaflow engine, which, as I just stated, is as economical as some of the very largest steam turbine units.

History of Development

The unaflow engine was conceived, I believe, in 1907 or 1908 in its present form. The idea really is old, but in its present form it dates from either one of those years. Since that time en enormous number of unaflow engines have been installed in Europe. I have no definite information as to the number, but a real start with the unaflow engine was made in the United States only as late, as I think, 1913, and since that time there have been installed under all kinds of conditions in the United States over one thousand engines. They aggregate approximately 350,000 horsepower. This showing will probably surprise a good many.

The old types of steam engines, the old slide valve engines, or, further back than that, the old engine of Watts type used approximately, ranging from 60 to 200 pounds of steam, per indicated horsepower, per hour; and efforts were made right from the start to improve the economy of these engines. There were two important causes for the lack of economy, that is, low steam pressure and lack of high vacuum. Steam pressures have been raised until to-day we have central stations which work on pressures up to 350 pounds. There are large steam turbine plants. Condensers have been perfected until to-day steam turbines operate with a vacuum as high as 29½ inches, or within half inch of the theoretical possible vacuum. This all shows that the source of economy, is increase of pressure, or, to put it more scientifically, increase of the temperature range through which the steam passes.

Cylinder Condensation

Unaflow engines, however, tackle an entirely different cause of loss. Every practical engineer who is acquainted with the steam engine is familiar with the term "cylinder condensation" and in a general way it is well understood what that term means. When you put steam into a cylinder under ordinary conditions, at say, 350 degrees, according to the steam superheat conditions; this steam will impart heat to the cylinder wall and will cool as it expands. If it is expanded down to the pressure in the condenser it will cool down to the temperature in the condenser, which with a high vacuum, is around 100 or 120 degrees. There you have a range of over 300 degrees in temperature. It stands to reason that by the time that steam has been exhausted from the cylinder, the cylinder will not have the temperature of the incoming steam; but while it is warmer than the exhaust steam it will be cooler than the incoming steam. The temperature will be somewhere in between. Then on a new stroke, when the steam is admitted, it comes in contact with the cooler cylinder walls; and the natural result is condensation of a certain portion of the steam, which, of course, can't do any further work. When the strokes follow each other at the rate of anywhere from 75 to 300 times a minute, the temperature influences are very marked.

In order to avoid this loss one of the most remarkable steps in the development of the steam engine has been taken in compounding engines. If you compound an engine in such a way, which is the best illustration of our case, that the temperature range of about 300 degrees is cut in half; in other words, the temperature range in a high pressure cylinder is, say 150 degrees, and in the low pressure cylinder the temperature range is the same; then the temperature differences between the cylinder walls and the incoming steam are cut in half. The cylinder condensation is also cut in half and the economy is improved. It is a matter of everyday experience that the compound engine is much more efficient in steam economy that the single cylinder; and the triple expanding engine is still better, while the quadruple expanding engine is supposed to be better, although there are other sources of loss which makes this doubtful.

Unaflow Construction

The unaflow engine was in the beginning an attempt to obtain the economies of the compound engine in a single cylinder. From the practical point of view, the outstanding feature of the unaflow engine is its central exhaust belt. The central exhaust port is the one distinguishing feature of the unaflow engine. You have in the center a hollow band or a belt, arranged around which are a number of ports. At the center there are a number of holes cored into the cylinder and a steam-jacketed head is fitted, which is usually notched in, but these details are not of any consequence in our discussion.

The piston is almost as long as half the stroke, and starts with a properly proportioned clearance. The length of piston is half the stroke minus the width of the cylinder ports. You can see as this piston moves it will finally overtravel the exhaust port. When steam is admitted the piston moves a certain distance, at which point the steam is cut off, and then expands up to the second point, where the piston over-travels the exhaust port. At that moment the exhaust starts. While the exhaust can only be short, because the piston returns and cuts off the exhaust; still this is the time during which the piston travels most slowly, that is, when the crank goes through the dead center; and while this in general practice is only about one-tenth of a stroke, in time it represents about one-quarter revolution or about 90 degrees of crank motion, so that the steam has plenty of time to exhaust. In the diagram it looks like this. The clearance is usually proportioned so that the compression just reaches the initial pres-

sure. During compression the steam is heated. Air is heated in compression and so is steam. If the steam is wet it is dried and if it is dry it becomes greatly superheated. In actual practice, as has been proven by experiments, the compression space is filled with steam which is a good deal hotter than the incoming steam. When the new charge of steam is admitted, there is no cylinder condensation. On the contrary, a part of the heated steam is driven back into the steam pipe. This is theoretically the basis of the unaflow engine elimination of cylinder condensation, but here enters a peculiar fact.

If you built an engine embodying nothing but the things which I have emphasized, that engine would be no more economical than a common engine. This is a surprising fact and shows that any theoretical deduction of this kind needs the correction of hard practical fact in order to make it workable; and that hard practical fact in this case is the addition of a head jacket. To-day, the typical unaflow engine is the combination of an engine with a central exhaust and a head jacket. If you leave off the head jacket you have nothing, but with a head jacket, when you expand to the end of the exhaust period, you have steam, which is about in the condition of that in the condenser; but this steam is continually in contact with the jacket heated by steam of the boiler temperature, so that it becomes heated. Any moisture present is driven towards the exhaust and out, so that the steam is dry. When compression begins and the steam becomes highly superheated, the interior of the clearance space is a good deal hotter than the incoming steam. In other words, you have the principle of the unaflow engine, exaggerated, and this makes for economy.

Another peculiar fact emphasizes the point that theoretical features need practical correction. Suppose I were to build a unaflow engine for non-condensing operation. If I take a volume of steam equal to nine-tenths of the stroke as atmospheric pressure and compress it into a clearance to obtain initial pressure, that clearance will have to be very large. Engines of that kind have been built that have clearances up to 14 per cent. Every practical engineer knows that large clearance is one of the things that destroys steam engine economy. If you want to study this in its reference to the unaflow engine; to design such an engine that will give good economy, with large clearance, you must have an engine of extreme size, because you must work with a very low pressure.

An engine was built for non-condensing service, but the clearance was made so small that the pressure at the end of the compression stroke would greatly exceed the initial pressure. In order to offset this an additional exhaust valve was placed in the engine, and was kept open during part of the return stroke. This is a clear violation of the unaflow engine principle; but reducing the clearance gets a better mean effective pressure and increases the economy. That part of the unaflow engine principle which obstructs is sacrificed. The result is a smaller engine that has exactly the same economy as the larger unaflow engine of large clearance.

As a matter of fact, the leading unaflow engine builders to-day use four valves in addition to the central exhaust port. The opening of the exhaust valve is adjustable so that the engine can be suited to any exhaust condition.

Unaflow Engine Economy

With a non-condensing engine operating on saturated steam under 100 pounds initial pressure, you can obtain an economy of 23 pounds of steam per indicated horse-power hour. That is excellent if you compare it with saturated steam, 100 pounds, non-condensing engine of any other type. As you improve the steam pressure and superheat conditions the economy improves. If the pressure is 200 pounds, and other conditions the same, the steam consumption is cut down to 18 pounds. At 100 pounds initial pressure with 100 degrees superheat, this engine will consume at the best mean effective pressure about 20 pounds. At 200 pounds pressure this is reduced to about 16 pounds.

The condensing unaflow engine, using saturated steam, of 100 pounds initial pressure, and with 27 inches of vacuum, the steam consumption is about 13½ pounds per indicated horsepower. If the pressure is raised to 200 pounds, other conditions the same, then the steam consumption will be about 12½ pounds per horsepower hour. Using 200 pounds pressure and 100 degrees superheat the steam consumption will be just a shade over 10 pounds per horsepower hour. This equals the best turbine practice in the country.

These are figures of actual practice to-day. They are guaranteed by the manufacturers of the unaflow engine. Some engines have been built by some famous European builders like Sulzer Brothers of Switzerland that have shown a steam economy of 8¼ pounds per horsepower hour, under ideal refined test conditions. You could not get figures as low as that in regular practice.

These figures are the steam consumption of a unaflow engine at the best mean effective pressure. You know the economy of any engine is best at a certain load and usually as you increase the load the economy is less and when you decrease the load the economy is less. In a compound engine the loss of economy due to deviating from the standard load, the best load, is very marked. If you overload a compound engine the economy is all gone. If you only partly load it your economy is also low. With the unaflow engine this is practically overcome. It has what the engineers call a flat economy curve. If you plot it on the basis of the load you will find that you will have only a very slightly curved line.

I have figures taken from tests under commercial conditions on two small engines driving a 100-kilowatt generator. One was of the condensing and the other of the non-condensing type. On the condensing engine, when the load was increased 50 per cent. the steam consumption increased 3 per cent. per indicated horsepower hour. At a quarter load the steam consumption was 7 per cent. higher. The non-condensing engine did not do quite as well. The record on that engine shows that for 50 per cent. increase of load the steam consumption increased 8 per cent. and for quarter load it also increased 8 per cent. over the best.

But this flat economy curve has a peculiar commercial influence. To-day when an engine is built for 100 kilowatts, it is not proportioned so as to have the best economy at 100 kilowatts; but the engine is reduced in size so as to give the best economy at approximately two-thirds of rated load. This means that the engine costs a good deal less and if you take into consideration the economy, the money invested and the repairs and upkeep; the engine is more economical than a full sized engine which would give a lower steam consumption at the rated load. That is regular commercial practice to-day.

But the flat economy curve has another influence. Take a compound engine and reduce it just as highly as you know how. Heat the receiver and take all the other precautions and you will improve the economy of the engine. You can build that engine so as to show a better economy than the commercial unaflow engine, but just as soon as you have any variation of the load, the unaflow engine will show a better steam consumption economy than the compound engine.

(Presented at the annual meeting of the National Association of Practical Refrigerating Engineers.)

The Elk Fire Brick Company of Canada, Ltd., Sun Life Building, Hamilton, have issued a bulletin describing their products. This company manufacture refractory brick in all shapes, for furnace linigs, blast furnaces, cupolas, fire brick arches, checker brick, etc. The catalogue illustrates every different shape, and gives information on the sizes available, and the guarantees given, also the deviations from specifications allowed. The shapes shown have been adopted by the Refractories Manufacturers' Association as standard. In addition to the foregoing there are a number of tables showing numbers of bricks required of various shapes to make certain size linings. Other useful tables are fusion points of different materials, and comparison of the different thermometer scales, circumference and areas of circles, and weights of various materials.

A Course of Instruction For the Graded Certificate

Some More Examples of Zeuner Diagrams and Comparative Indicator Cards—Obtaining the Clearance From the Indicator Card—Method of Computing the Weight of Steam Consumed Per I.H.P. Per Hour

By T. H. FENNER

HAVING in our last article made some further explanation of the Zeuner diagram, we will in this one show some diagrams with theoretical indicator diagrams drawn from the Zeuners. We should perhaps not call these theoretical diagrams, as they are not constructed quite according to the theoretical law of steam expansion, but rather the diagrams that we should expect to get from a valve with the dimensions of inside and outside lap and the angular advance as shown in the Zeuner diagram.

The first figure is a Zeuner diagram of a valve with normal characteristics cutting off at about three-quarter stroke. It must be remembered that with the ordinary slide valve it is not possible to get cut off very early, in fact not before half stroke, without affecting very greatly the other events. When we wish to get early cut off we have to resort to special means, such as expansion valves on the back of the main valve, special drop cut off valves, such as the Corliss, or the automatic cut off worked by the centrifugal governor.

The four cards here shown afford a means of comparing the effect of different amounts of lap, angular advance, etc., on the steam distribution. Fig. 2 shows the effect of increasing the angle of advance and adding outside lap, and also inside lap. This is done in order to get an early cut off, while keeping the release and compression within reasonable limits and also keeping the lead fairly early. Here we have cut off occurring at half stroke, with release a little earlier than it was in the last card, while compression is earlier, and admission a little earlier. Thus we see again that increasing the angle of advance makes all events earlier. The increased angular advance is not enough of itself to give the cut off where we require it, so the lap is increased. The exhaust lap is practically the same as in the first card, but we might have increased it a little, thus making release a little later and compression a little earlier. This diagram and card illustrate well the reason why a slide valve cannot be made to cut off before half stroke. To make the cut off any earlier with the same angular advance we should have to decrease the lead, while to make the release any later we should have to make the compression much earlier.

Fig. 3 shows the effect on the card of increasing both inside and outside lap, the angular advance being the same as in the first case. It will be seen that the lead is later, while the cut off is earlier. On the exhaust side of the valve release becomes later, while compression is earlier.

Fig. 4 shows the same thing with the laps both decreased. Here we have lead earlier, cut off later, release earlier and compression later. These figures and the preceding ones should have made the reader familiar with the Zeuner diagrams and to some extent with cards. Before going into the question of different forms of valves and valve gears, it would be better to see what other information an indicator card can give us over and above the distribution of steam.

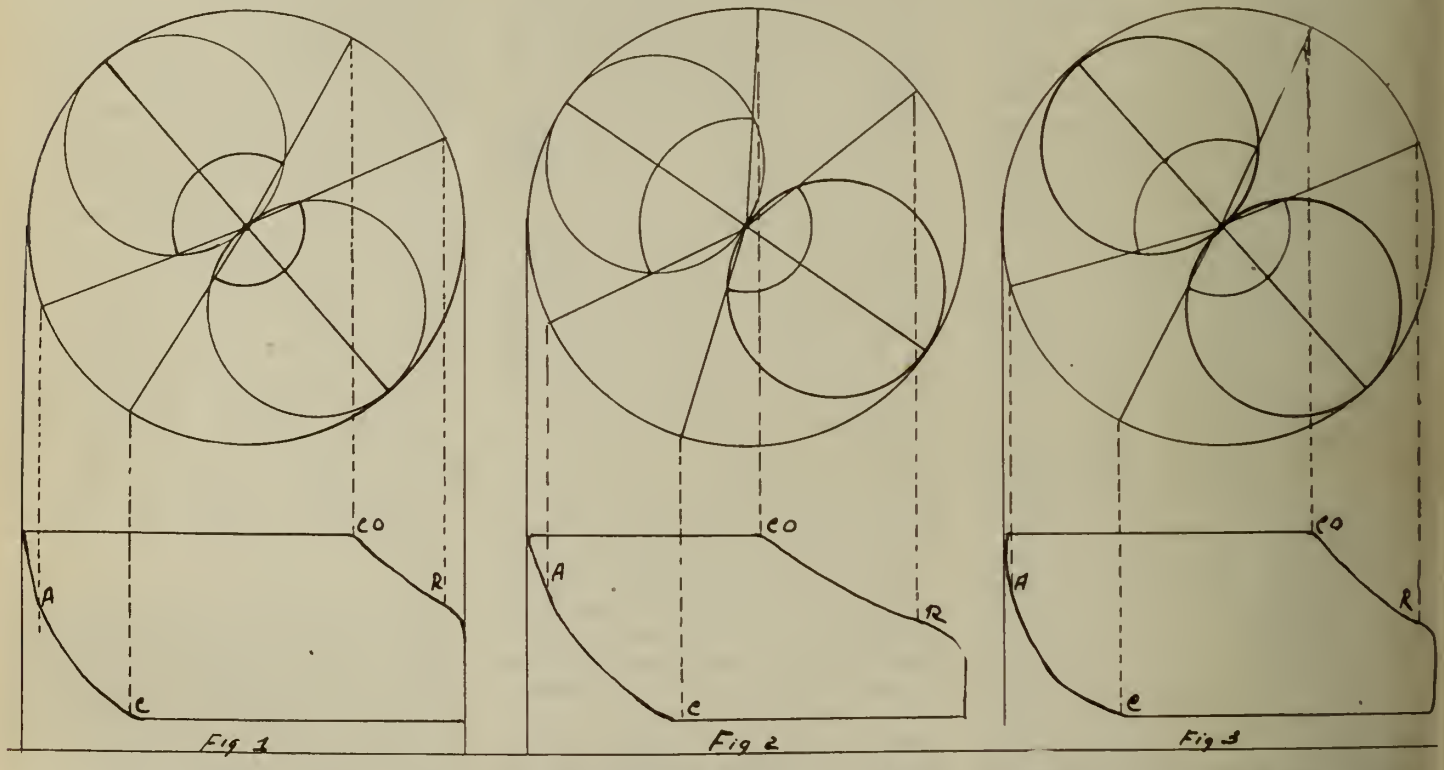

FIG. 1—NORMAL VALVE.

FIG. 2—INCREASING ANGLE OF ADVANCE AND ADDING OUTSIDE LAP.

FIG. 3—INCREASING INSIDE AND OUTSIDE LAP.

Some Uses of Indicator Cards

We have seen that the indicator card can be used to furnish us with the mean effective pressure of the steam in the cylinder, from which we can compute the horse power. From it we can also obtain the weight of steam used per stroke in the cylinder, and from that, of course, obtain the weight of steam per

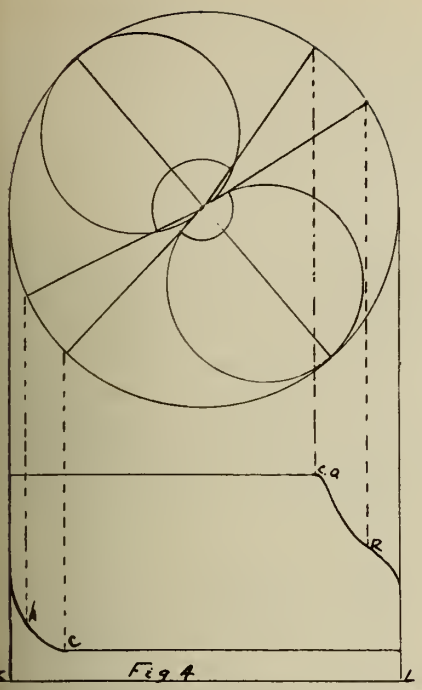

FIG. 4—DECREASING INSIDE AND OUTSIDE LAP.

I.H.P. per hour. We can also compute the amount of clearance, that is, the volume of clearance, and in the case of compound engines, we can see how closely the expansion in the different cylinders approaches the ideal expansion curve which would be made by the expansion of the same amount of steam in one cylinder. From this it will be seen that a good understanding of the indicator card is a great help to those engaged in the operation of a steam engine or steam engines.

Obtaining the Clearance

The clearance obtained from the indicator card is, of course, the clearance volume, and not the linear clearance between the piston and the head of the cylinder. It includes the space from the piston face to the valve face, and is expressed as a percentage of cylinder volume. The effect of the clearance in a cylinder depends on the way it is filled by the steam at every stroke. If the exhaust valve is allowed to close late in the stroke, so that there is practically no steam left in the cylinder, there will be not only a loss of cushioning effect, but the clearance space will have to be filled with fresh steam at every stroke, and this steam will be lost. That is a greater weight of steam will be discharged from the exhaust every stroke than if the exhaust closed in time to give cushioning. The exhaust closing should be arranged so that the compression curve mounts up to meet the admission line smoothly. The steam being compressed by the returning piston brings the moving parts to rest without shock, and besides that fills the clearance space with steam at almost the initial pressure, so that when the valve opens to admit steam just before the commencement of the return stroke, the clearance space is filled with steam at initial pressure. This keeps up the steam line in a horizontal position until cut off takes place, and the clearance space steam is retained in the cylinder.

The effect of the clearance on the expansion line can be shown as follows: Supposing we have a cylinder of 12 inches area and 12 inches stroke or one cubic foot volume. Let the clearance be 10 per cent. of the volume, then the total volume of cylinder and clearance space will be 1.1 cubic feet. If the cut off takes place at 4/10 stroke and the initial gross pressure is 100 lbs. when the pressures for the remainder of the stroke will be found from Boyle's Law, and will be at 5/10 80 lbs., at 6/10 66.6 lbs. and so on, the mean effective pressure being 73.81 gross, and deducting the back pressure, 59.1, assuming atmospheric exhaust pressure. Now if we take into account the clearance we shall have cut off taking place at 5/11 stroke instead of 4/10. This will, of course, affect the expansion line and the mean effective pressure. We shall have at 6/11 a pressure of 83.3, at 7/11 71.4 and so on, the mean effective pressure in this case being 86.81 lbs.

However, this amount of steam that is in the clearance space will be compressed again on the return stroke, so that we will not actually gain anything by it. On the other hand, if it exhausted, we shall have used that much extra steam, and besides that will have lost the good effect of the cushioning, and introduced our admission steam into a cylinder and against a piston that has been so much longer in contact with the exhaust passage, and so we will get a larger amount of initial condensation. Therefore, it will be understood that compression fills a very important part in the good working of an engine.

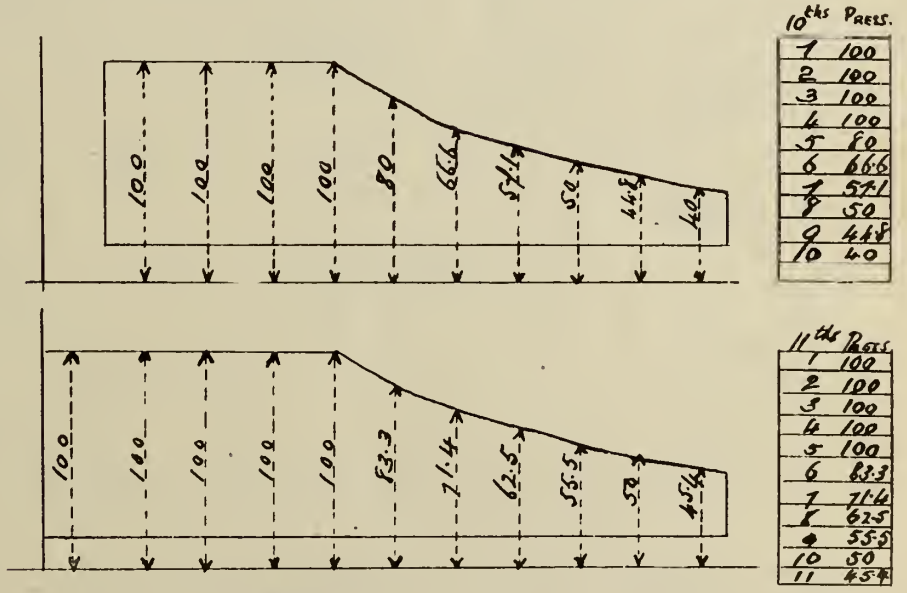
The method of finding the volumetric clearance from an indicator card is as follows. Select two points in the compression curve, and drop perpendiculars from them to the atmospheric line. Take the two points as far apart as possible. Join the two lines by a horizontal line from the lower point to the perpendicular from the upper point and complete the parallellogram. Draw a diagonal to meet the line of absolute vacuum. Where this line cuts the zero line erect a perpendicular, the distance between this perpendicular and the perpendicular dropped from the beginning of the stroke will represent the clearance in the cylinder. The diagrams following show the expansion curve (theoretical) when considering clearance and neglecting it.

Obtaining the Weight of Steam

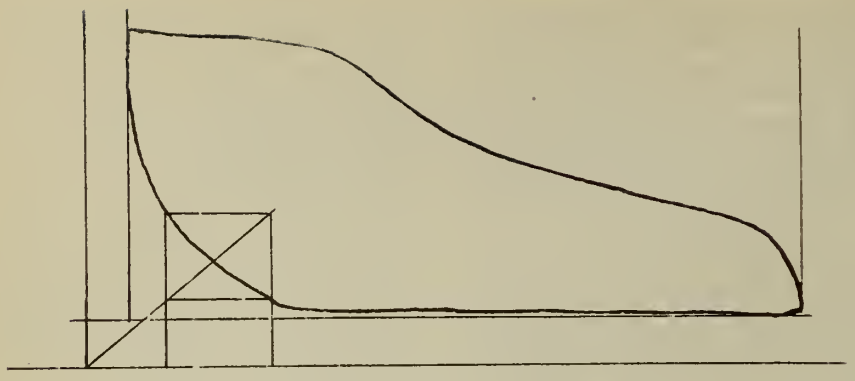
The indicator card being a graphical chart to scale of the pressure and volume of the steam in the cylinder at any moment, it naturally follows that the weight of steam used can be computed from the data furnished by the card.

If we take a point in the expansion curve just before release is effected then we have the volume of the cylinder and clearance up to that point. From the steam tables we can find the weight of a cubic foot of steam at the pressure (absolute) as measured on the card at the point taken. That is the weight of steam in the cylinder at that point, including the clearance steam. We now take another point in the compression curve and find the weight of steam contained in the cylinder at that point. The difference between these two amounts will represent the amount of steam rejected through the exhaust at each stroke. Knowing the horse power developed, we can find the consumption of steam per I.H.P. per hour by a simple calculation.

If the engine is developing 100 H.P. and running 120 strokes per minute, that will be 7,200 strokes per hour. If the consumption is, say, half pound steam per stroke, then there will be 3,600 lbs. steam used per hour, and the horse



M.E.P. WITH AND WITHOUT CLEARANCE.



METHOD OF FINDING CLEARANCE.

power being 100 the steam per I.H.P. per hour is 36 lbs. This can be expressed as a formula:

$$\frac{\text{weight steam per stroke x strokes per hr.}}{\text{I.H.P.}} = \text{steam per I.H.P. per hour}$$

The diagram illustrated herewith shows plainly the method of obtaining the weight of steam per stroke. The line Z Z^1 is the line of no pressure, and the line A L is the atmospheric line. D is the point in the compression curve, and E is the point in the expansion curve. The distance Z O is the clearance space, and O Z^1 is the total length of the stroke. Z Z^1 is the line of no pressure, and the length of the card five inches, which makes it easy to proportion, the clearance space being 10 per cent., we can proceed as follows: Let the initial pressure be 150 lbs. absolute, and the cut off at 4/10 of the stroke. Suppose the diameter of the cylinder to be 36 inches. The absolute pressure at release is 60 lbs. per square inch. The volume of the cylinder and clearance will be

3 x 3 x.7854 x 5 × 1/10 (3x3.7854x5)
=35.34 + 3.534= 38.874

The volume of steam contained in cylinder and clearance space at release will be

38.374 x 10/11=34.885 cubic feet.

The weight of a cubic foot of steam at an absolute pressure of 60 lbs. per square inch is .1394 lbs., so we have

34.885 x .1394 = 4.862 lbs.

If there were no compression this would be the consumption per stroke, but we have to deduct the volume of steam contained in the cylinder after the exhaust valve closes. From our point in the compression curve we find the volume of the cylinder and clearance at that point. This is practically 14 of the total volume, so we have

38.374 x .14 = 5.37 cubic feet

and using the factor for the weight per cubic feet we again get

38.374 x .14 = 5.37 cubic feet,

Deducting .748 lbs. from 4.862 lbs. we have 4.114 lbs. per stroke.

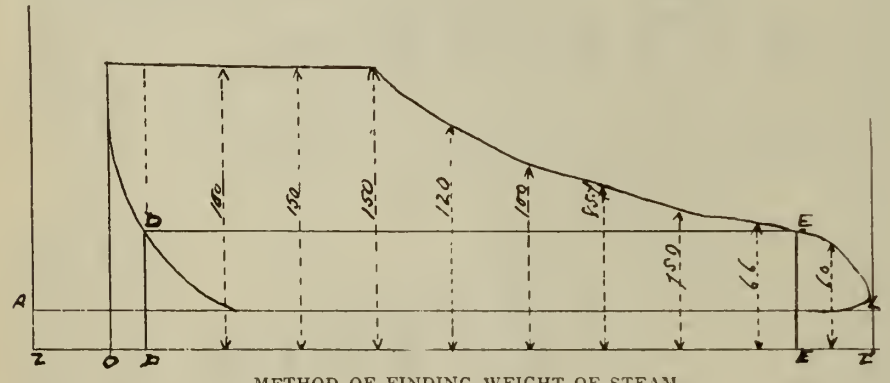
Suppose now that the engine is making 60 revolutions per minute, or 120 strokes. This will be 120 x 60 = 7,200 per hour. The weight of steam consumed will be

7,200 x 4.114 = 29,620.8 lbs. per hour.

The mean effective pressure measured on the card will be 110.73 — 14.7 = 96.03.

The I.H.P. will be

$$\frac{96.03 \times 36 \times 36 \times .7854 \times 5 \times 120}{33{,}000}$$



METHOD OF FINDING WEIGHT OF STEAM.

=1777.25 I.H.P.

The steam consumption per I.H.P. per hour would be

$$\frac{29{,}620}{1777.25} = 16.6 \text{ lbs.}$$

It will be understood by the reader that no such results as this would be obtained from an actual card, and one would hardly meet with just such an engine. The example is only chosen as an illustration, and serves to show the method employed.

Steam consumption from indicator cards cannot be depended on within less than 2 to 3 per cent. of an error. The only absolutely correct way to get at steam consumption is to weigh the water of condensation, or use a flow meter.

COUNCIL REFUSES INCREASE

The Saskatoon council at a recent meeting refused to grant any increases to the electrical men in the city power station, after a long discussion with a delegation representing the men. The men claimed that as the station was now on a paying basis, they were entitled to a fair wage, which they were not receiving, they asserted, when compared to other places in Western Canada. The council took the view that the city's finances were in such a state that it was impossible to grant any increases or to enter into any further liabilities. The question was put to the men by Alderman Blain as to whether they would prefer a cheque for $100 that would be honored or one for $150 which would come back marked N.S.F.

Plans are being prepared for a workshop costing $60,000 for the city of Ottawa. Tenders will be called shortly.

* * *

The Winnipeg Supply & Fuel Company, 405 Canada Building, are planning the erection of a warehouse at cost or $60,000.

* * *

The Gove Motor Car Company, Tilbury, Ont., are contemplating construcethe erection of a warehouse at cost of $50,000.

* * *

Work will be started in the near future on the erection of a foundry for the National Castings, Limited, Belleville, Ont.

* * *

An athletic stadium is to be erected on the corner of King Edward Avenue and York Street, Ottawa, at a cost of $350,000.

* * *

The Southern Ontario Gas Company have announced recently that they are planning to erect a large artificial gas plant at Dutton, Ont.

* * *

The McIlroy Belting & Hose Company, Hammond, Ind., are opening up a branch office at Kingsville, Ont., and will instal equipment to cost about $20,000.

* * *

Bought Leaside Plant.—The Leaside Munitions Company, Limited, have completed the purchase from the United States Government of the large plant erected at Leaside during the latter months of the war. This plant was built for the American Government by the Leaside Munitions Company for the manufacture of twelve-inch shells for the United States artillery, but the plant and its equipment had only been completed a few days when the armistice was signed, with the result that it was never put to its intended use. It will be used by the present purchasers for manufacturing purposes.

Erecting and Lining Up Steam Engines

Adjusting the Main Bearings—Fitting in the Piston—Various Types of Crossheads—Getting the Shoes Adjusted—Finding the Correct Length of Connecting Rod

By "FITTER"

AFTER the shaft has been tested for alignment with the cylinder and found correct, the main bearing side pieces and caps are put on. Most engines for heavy duty have the main bearings made in four parts, and the side pieces are adjusted by means of wedges and studs, the caps being held in the usual way by a heavy cast iron bearing cap. The best way to adjust the top quarter is by means of taking leads from bearing and fitting shims under the cap to give just the requisite pressure when the nuts are tightened up. The side pieces or quarters are adjusted by pulling up on the nuts until they are just comfortably tight by hand, when they can be further tightened up by a short spanner, the amount of weight to be put on the spanner being a matter of judgment. Probably the best way to adjust the side pieces is to pull them up by means of a short lever placed under the nut, and then run the nut down tight by hand, and leave the final adjustment till the engine is running. This allows one to feel by the action of the studs just when the quarter piece is tight, as when there is any slack a jumping action will be felt on the studs, which will gradually disappear as the wedge tightens up. The back pieces should be fixed first and the front one brought up, to suit. However in the erecting shop the quarter pieces can be adjusted by tightening up, and the crank shaft tested again by the line when everything is tightened up. It is quite possible to throw the shaft out of line by tightening the outboard bearing up more than the inner one, or vice versa, but in order to do this it would be necessary to put some weight on the spanner with which the adjusting nuts are tightened up.

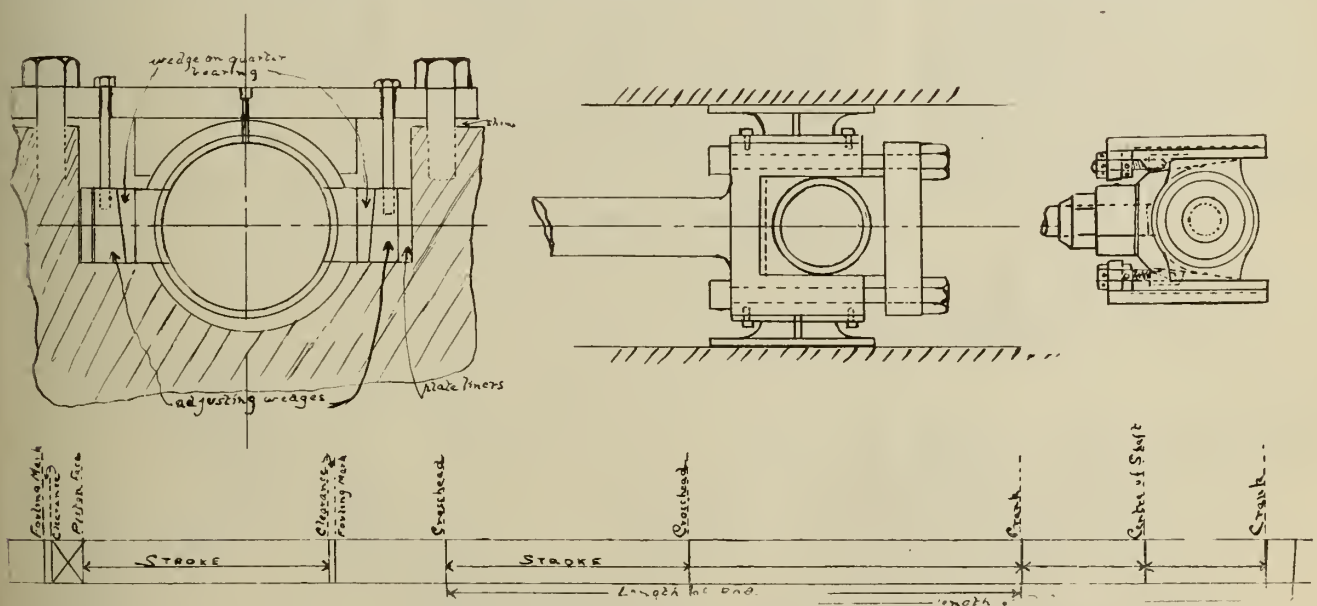
To fit the top quarter three pieces of lead wire are laid on the shaft, and the brass put down on these, the cap, being then put on and tightened up. The nuts are then removed, the cap and brass lifted again, and the leads examined and gauged for thickness. They should be about 28 to 30 gauge, and if they are any finer than that, shims should be put under the lugs of the cap in order to relieve them, and allow the nuts to be tightened down properly. It is a mistake to allow bearing caps to run loose because the nuts cannot be tightened up without heating up the bearing.

The various parts of the bearings, consisting of the four bearing quarters, the wedges, quarter plates, etc., should be all typed with numbers corresponding at their edges, so that they can be put back in their right place when the engine has to be re-erected. Letters or numbers can be used, so long as a definite scheme is adopted and adhered to right through. Most engine builders adopt the plan of using the order number of the job and the part number on each piece.

Having got the crank shaft properly in place and the bearings adjusted and tightened up, and the shaft checked up for alignment, the line can now be removed, and the piston and rod put in place. The piston rod may be made with the crosshead as part of the rod, or it may be made and usually is in stationary engines with the piston rod end screwed for the reception of the crosshead. Naturally it will make a great difference which way the rod is made as to the way it is put into the engine. If made with a solid end, the rod must be passed into the cylinder through the stuffing box, and the piston placed on last, or the rod will be passed through the cylinder from the cover end, with the piston already assembled to a certain extent, and the crosshead screwed on after.

The amount of assembling on the rod that the piston will have had in the latter case will depend upon the form of the piston packing. If piston is furnished with Ramsbottom rings, the rings will be in place when the piston is put on the rod, while if the construction is a built up one, the rings will be assembled on the piston after it is placed in the cylinder, and the junk ring or follower placed last.

The form of the crosshead will also make a difference in the method of erecting. If the crosshead forms part of the piston rod, then the piston rod must be centred in the guides, and gauges made for the distance of the slippers from the crosshead faces to the guide faces. If the crosshead is of the screwed on type, and the guides are bored for circular shoes, the shoes will be most likely fastened to the crosshead in such a way that they can be adjusted by means of



MAIN BEARING ARRANGEMENT—SOLID TYPE CROSSHEAD—CROSSHEAD WITH WEDGE SLIPPERS—STAFF FOR GETTING CONNECTING ROD LENGTH.

a stud, which draws them further on the crosshead or pushes them further out, at the same time making them wider or narrower relatively to the guide faces.

We shall review these operations in a little more detail. Suppose that we take the piston with the Ramsbottom rings, and a piston rod fitted with a screwed crosshead, which is by far the most usual type to be met with in horizontal stationary engines, and in many vertical ones also. The guides on vertical engines are, however, not made circular. The first job is to pick up the piston and rod, the piston being fitted onto the rod but without the rings being in their place. The rings will have been finished and cut to the right length and fitted in the cylinder before the cylinder came into the erecting shop, but it is usually a safe thing to try them in and see that they are not too long before placing the piston. Placing the rings on the piston if they are of usual Ramsbottom type is a simple matter, the only thing required being care. There will be three rings as a rule, and by placing the bottom one on first before the piston is taken to the cylinder, there is only one ring the middle one, that has to be passed over a groove before reaching its own. In order to do this a few pieces of thin tin are placed over the first groove at different parts of the circumference so that the ring will not slip into it while being passed over. The ring is placed on the piston, and pushed down slowly and evenly till it reaches its place. Putting on a big piston ring is no different to putting on a 4-inch piston ring, the only thing necessary being care and patience.

If the piston is of the built up variety the ring may be one single broad ring or it may be a sectional ring with a spring to each section. In any case the piston is entered first and the ring put on after.

The Ramsbottom rings having been fitted, we are now ready to enter the piston and rod in the cylinder. In order that we may not damage the screwed end of the rod while passing it through the neck bush of the stuffing box, it is better to land the piston and rod on blocking at the cylinder end, so placed that the piston is just at the mouth of the cylinder while the end of the rod is not quite up to the neck bush. The piston should be entered into cylinder by edging it gently along with a bar and at the same time a man at the stuffing box end should try and guide the rod end so that it does come fair with the cylinder neck bush. It may be necessary to see that the rings do not enter the steam ports and if this is the case, strips of sheet iron are placed across the piston rings and ports so that the rings are kept down until they have passed the danger zone. Here again ordinary care is needed in entering the piston and rings, and if anything seems tight, a careful investigation should be made before any rough tactics are resorted to, or patience is lost. This warning may seem superfluous, but in the writer's experience several cases of damage have been done by the too hasty application of a big bar or an impatient blow with a hammer.

When the rings are safely entered, and the rod end is also safely passing through the stuffing box, with no threads burred up, the rod should be shoved through until it is half way along the guides, that is, the piston is about in the centre of the cylinder. The rod should now be centred in the guides, and this can be done by callipering from the centre which will be in the end of the rod to the top and bottom of the guides. This distance can be checked up after the rod is found to be central with the distance given in the drawing, and once the rod is correctly set, it should be blocked top and bottom. When dead central in the guides, it should also be absolutely horizontal, so that the spirit level here gives another check. The crosshead jam nut should now be run on the rod, and the crosshead without the shoes screwed onto the rod. It should be run on the rod until the rod end shows through the crosshead just flush, and the nut run down till it just touches the crosshead. The bottom shoe should now be put on and adjusted until it is just supporting the rod. The top shoe can now be put in place and the rod callipered, and the shoes adjusted if necessary until the rod is dead central in the guides. The adjustment is easily made by the wedge shaped formation of the shoe and crosshead, and the adjusting screws.

If the crosshead had been of the solid type, we should have had to proceed in somewhat different manner. The piston rod would have been entered through the stuffing box and the piston put on the tapered end and the nut tightened up, after which the rings would have to be fitted. The rod would then be blocked up central in the guides, which would have been flat instead of bored out, and gauges made for the width of the crosshead slippers. This type of crosshead is more met with in marine and vertical stationary engines than in the ordinary horizontal Corliss type.

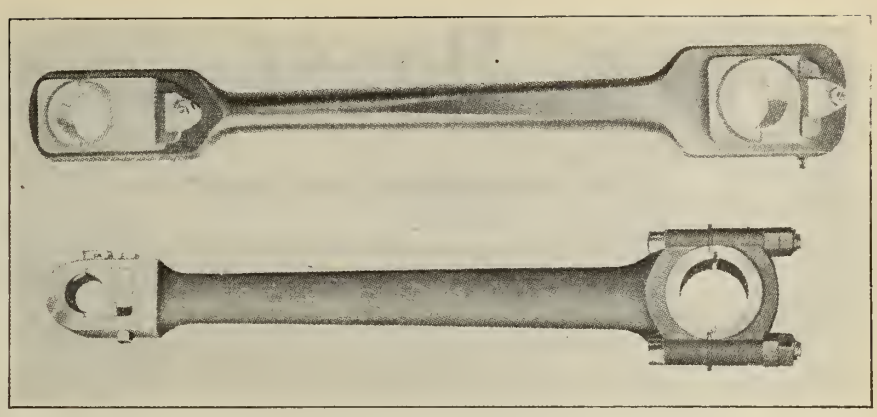
After the gauges had been made, the shoes would have to be put on the planer and machined down to the required width. In this type of crosshead the wear is taken up by liners while in the type we first dealt with the shoes are adjustable on the crosshead in a very easy way. Making the gauges is a fairly simple matter. After the crosshead is centred, pieces of 1-16th flat iron are taken and carefully fitted in between the crosshead and the guide face, being filed down as necessary until they are a nice sliding fit. The gauges are then passed on to the machinist who then marks off the crosshead shoe to correspond with the width of the gauge.

Getting the Connecting Rod Length

After the piston rod and crosshead are assembled, and the guide shoes fitted, the next job will be to put the connecting rod in place. Before this is done, the length must be checked up on the job. That is the length between centre and centre of crosshead and crank pin. The connecting rod may be made with box ends in the marine style, or the bottom end, usually called the big end in stationary work may be of the box type, while the small end is of the gib, strap and cotter type. In any case, it is usual to make a staff showing the exact distance from crosshead pin to crank pin when the piston is at each end of its stroke. It is obvious of course that in an arrangement where the crosshead is screwed onto the piston rod, there is ample room for adjustment, while in a solid crosshead arrangement any discrepancy in the length would have to be made up with liners, or if too long, by planing off the foot of the rod.

A staff is made long enough to cover the whole length of the engine and first of all the cylinder length is marked on it from cover to cover. This can be obtained without much trouble. A line is marked on the staff representing the cylinder face, and then the distance the cover projects into the cylinder is marked away from the first line. That is the fouling mark at the head end. The piston is then pushed down the cylinder until it strikes the end of the cylinder, and the distance it measures from the cover taken. This distance plus the thickness of the piston which is of course known gives the fouling mark at the opposite end of the cylinder. The staff is now laid down alongside the engine, and the line corresponding to the cylinder face placed just flush with the end of the cylinder, by means of a straightedge laid across it. By dropping a plumb bob down across the centre of the crank shaft, and squaring across from the bob, the centre of the shaft can be transferred to the shaft. Lay off on each side of this centre mark the length of the crank, and you have the two dead centres of the crank pin centre. Assuming that the crosshead is screwed up on the piston rod so that the rod just comes flush, there will be several threads left for adjustment. If the piston is now pushed hard up against the front head of the cylinder, and the centre line of the crosshead pin measured on the staff the exact length of the rod from piston to crosshead centre will be obtained. Now mark on the staff at each end the amount of linear clearance of the piston from the cylinder heads, remembering that as the engine wears the piston will approach the front so that there should be a little more clearance at the front head than the back. Suppose that the clearance at the head end is 1-8th and the front 3-16ths. Mark these clearances on the staff, by lines at these distances from the fouling marks. Now it will be plain to see that if we lay off the length of the piston and rod to the centre of crosshead pin, the distance from the clearance mark to the crank pin dead centre will be the length of the connect-

ing rod centres. This distance measured from the outer dead centre of the crank pin should give the right clearance on the front end of the cylinder, but if it does not, the crosshead may be adjusted either in or out on the rod just half the necessary amount, till the clearances are correct at each end. With a solid crosshead the discrepancy would have to be taken up on the centres of the connecting rod, and therefore the rod is never made up until the length has been secured from the engine in the manner just described. The accompanying diagrams will make the points mentioned in this article easy to follow.



TYPES OF CONNECTING RODS.

A 1,000,000 HORSE-POWER HYDRO DEVELOPMENT

THE water level of Montreal is now about 24 feet above the sea-level, and ocean going steamers reach Montreal without using any locks. Lake St. Louis is about elevation 76.

My project is to build a dam in the Lachine Rapids at Isle Heron, holding the water to the Lake St. Louis level. By putting locks on the north side of the river, ocean vessels will then be able to reach Lake St. Louis. But in order to reach the locks, it will be necessary to dredge a channel as wide, as the St. Lawence River at Montreal, up to this dam.

By doing this we could reclaim ten square miles from the bay or wide part of the river between Montreal and Lachine. This bay or widened river has been responsible in the past for the accumulation of frazil and other ice and frequent floods in the lower part of Montreal. The land thus reclaimed would afford Montreal a badly needed manufacturing site and would be connected with the city by ample tunnels. This project, the late Sir William Van Horne stated shortly before he died, would make Montreal one of the greatest ports in the world. Especially as the dam would enable us to develop one million horsepower a year, or the equivalent of ten million tons of coal a year.

This project should be of vital interest to the city of Toronto, or as a matter of fact the whole of Canada. First, because it would insure the early canalization of the St. Lawrence River, permitting vessels of 30-foot draft to reach the Great Lakes. It would also be of vital importance to the whole Province, as it would also enormously decrease the cost of many manufactured articles, just as the five Pioneer Companies at Niagara Falls practically made aluminum and other articles accessible to the great mass of people by enormously decreasing the cost of manufacturing them.

A former president of the New York Central Railroad once stated to me that people thought that the New York Central Railroad was opposed to the Panama Canal, which objection he said would be most stupid. For the building of the Panama Canal could not but help build up the entire Pacific Coast, and that anything which built up the Pacific Coast would enormously increase the business of the Transcontinental Railroads. He might also have added that it would benefit the entire continent by reducing the cost of handling commodities.

It seems a crime that there should be any delay whatever of the development of these two rivers. At the same time,

Women in Engineering

ONE of the results of the war was to introduce women into fields of endeavor that had been formerly strictly a preserve of the sterner sex. Now that the war is over, and in places peace has settled down, women show signs of wishing to keep up the work that they learned so well during the strenuous days of the war. In this connection the Women's Engineering Society, an institution formed in England during the war, in casting about for a means of utilizing the services of women who were trained in engineering, have formed a company known as the Atalanta Company, Ltd., in which the whole staff executive and works, and all the labour is of the weaker, or as Kipling would say, the deadlier sex. The works have already secured several contracts, including the making of glass machinery, atomisers, etc. The capital is entirely put up by women, and the Board of Directors includes Lady Parsons, Miss Caroline Heslett, who is secretary of the Women's Engineering Society, and Lady Shelley-Rolls. This is a long step ahead for the ladies, and if they make a success of it without any assistance from the more experienced male engineers and business men, they will have a lot to be proud of. We are, however, very doubtful of the success of such an enterprise if wholly managed by women, and our suspicions are justified by the fact that in the Board of Directors there appears at least one man, who is a principal of a technical college. This looks as though the ladies were not above accepting some advice now and again. There is no doubt that during the war women gave of their service unstintingly, and were deserving of great praise, but we believe that now is the time for them to retire gracefully into their various pre-war spheres. We believe with all respect to the fair sex, that there are other pursuits more suited to their abilities than that of engineering. We shall watch the progress of the experiment with interest.

Another Power Proposal

WE have illustrated in another part of this paper a further water power development suggested by Mr. Kennard Thompson, the Canadian engineer who recently described his plans for damming the Niagara River, and tunnelling Goat Island, in order to procure some 4,000,000 H.P. The plan discussed in this issue is to be carried out further down the St. Lawrence, near Montreal. Here the author proposes to erect a dam to utilise further the 50 feet of fall available at Lachine Rapids and to do so without interfering with the navigation of the St. Lawrence in any way. In dredging a channel to approach the locks that would be built in order that steamers could reach Lake St. Louis, some ten miles square of land would be reclaimed, which could be used for industrial purposes. Hence a great manufacturing district would be induced, supplied with cheap and abundant power. The estimated power would be 1,000,000 horse. It is of course impossible to pass an opinion on such plans as this and the Niagara River project without the very fullest information, but there is a breadth of vision and a confidence of success about these proposals which commend themselves to our opinion. We believe that this is the way to go about developing the vast powers that we have so that they will benefit the country at large.

The Perpetual Air Compressor

WE were somewhat disappointed this week at not receiving a host of letters from our readers pointing out where the inventor of the air compressor described in our last issue had gone astray. To any engineer in a power plant where there are reciprocating engines, the mistake made by this deluded Grecian gentleman should be obvious. Any man who possesses a first or second class certificate of competency as a stationary engineer in Ontario should be able to prove by a simple calculation that the claims of the invention are based on a wrong impression. The very first figures given by the inventor as to the number of foot pounds required to compress one cubic foot of air to a pressure of 10 atmospheres are quite wrong, and show that he has no grasp of the subject that he claims to know all about. Surely he cannot get away with such wild statements before an audience of stationary engineers such as the readers of Power House.

Progress in New Equipment

PRODUCTO COMBUSTION GUIDE

The Producto Combustion Guide, which is a recent development of the Progress Products Company, 1313 Race street, Philadelphia, Pa., claims to make it possible to eliminate the costly waste caused by excess air by pointing out at a glance improper combustion conditions such as too thin a fire or holes in fire. The Guide also reports conditions where too thick fires or clinkers are causing losses due to incomplete combustion.

Since the instrument not only tells when conditions are not ideal, but also reports what to do in boiler operation, the fireman is guided every minute of the day in the setting of the dampers and the control of the fire. Other inefficient firing conditions, such as excessive soot on tubes, broken baffles and leaky settings are also pointed out definitely as soon as they begin to develop. The power loss due to these causes is the greatest part of the preventable power loss and totals about 25 per cent. in the average plant.

Pressure differences, due to both steam and air flow, vary as the square root of the velocity. The other factors involved, although different, are constant for a given condition, and the differences are compensated for in the instrument by three nests of variable adjusting tubes, which, by controlling the areas in the liquid reservoir and consequently the relative movement of the different liquid levels, make the alignment a simple proposition. The liquid level in the upper tube moves in proportion to the steam flow; those in the lower tubes in proportion to either the quantity of air flow or to the change in resistance to flow either through the boiler tube or the fire bed.

By means of these adjusting tubes the movements of the indicating liquid columns are equalized when the boiler on which the instrument is being installed is operating efficiently. Thereafter for good operation these levels should be in line. Different out-of-alignment combinations indicate different inefficient furnace conditions which can be remedied immediately by the fireman controlling the fire, air supply, etc., so that the alignment is restored. This instrument combines the advantages of a steam flow meter and multiple differential draft gage with a tell-tale idea.

The body is cast iron and the indicating tubes which are usually found in instruments embodying the idea of inclined liquid passages have been replaced by machined slots in the cast iron, which are covered by special Safetee glass. The slots in which the liquids travel are white porcelained, so that the levels are plainly visible. The special gasket used has printed upon it instructions in the use of the instrument, including diagrams of the liquid level combinations when improper conditions are prevailing.

The combustion guide is made in two standard types which will meet all existing boiler room conditions—natural draft type and forced draft type. The forced draft type has the same liquid passages as the natural draft, and an additional non-adjustable one, which, being really a draft gage, gives the pressure conditions over the fire in inches of water. The steam passage contains mercury and the air passages colored oil. The steam indication is actuated by the difference between leading and trailing pressures transmitted to the mercury

BREAKDOWN OF A TURBO ALTERNATOR

The following letter from the Metropolitan Vickers Electrical Co., Ltd., England, to the "Engineer" contains an interesting account of a breakdown somewhat unusual in its nature, and the means adopted to correct the liability to a similar recurrence:

On the morning of December 8 one of the new 15,000 K.W. turbo-alternators at Dalmarnock Station, Glasgow, broke down after being in commercial operation for about two and a half months. The insulation on the windings at one end of the machine took fire and as the machine could not be stopped for some twenty minutes, the whole of the insulation on this end of the machine was destroyed.

No evidence could be found at the time as to the cause of the breakdown. The machine was very heavily insulated and every precaution had been taken with regard to winding and testing. As another generator was almost ready for service, it was substituted for the first machine, and, although the breakdown occurred on Wednesday morning, the new machine was in position, tried out, and put on load the following Wednesday.

After operating on commercial load for about a week sparks were seen issuing from the top of the stator frame, and the machine was shut down. The windings were found to be in perfect condition, and the machine was run up again with field on, when sparks were again noticed, and further examination showed that one of the insulated bolts through the core had broken down near the endplate. These bolts pass through the core in an axial direction, and serve to hold the endplates tightly against the laminations. The bolt was removed, and it was found that it had vibrated violently and the insulation had broken down near the centre of the core as well as near one end. The windings were found to be in perfect condition, but an inspection of other bolts which had not given trouble showed that vibration of a more or less serious nature had occurred on several of them.

A series of tests and investigation was at once undertaken, and it was found that for the particular length and diameter of bolt used a relatively slight tension was sufficient to bring the frequency of the bolts to such a value as to synchronize with the frequency of vibration of the whole set, corresponding to the speed of 1,500 revolutions per minute. A further and more careful inspection of the first machine which had broken down showed that the breakdown was due to a similar trouble, as it was found that one of the bolts had broken down to the core, and molten metal had come into contact with the insulation at one end of the machine, thus setting it on fire.

A third generator was practically ready for running at the time the first breakdown occurred, and it was decided to remove the steel core bolts and replace them with copper bolts of smaller diameter which would carry heavier insulation. These bolts are stressed to such a low value as to leave their natural frequency very far below the running frequency of the machine. A considerable amount of work was required in order to replace the bolts, but this was done in an exceptionally short time, and before the end of the month the work had been completed and the machine was under load. Since this time it has carried peak loads up to 21,000 kilowatts. The two machines which broke down are being rewound, and will shortly be in commission.

The use of core bolts has been standard practice on the part of many companies in this country, America, and on the Continent. Machines have been in operation for fifteen years in which this construction has been used, and the Westinghouse Company of America has a very large number of machines in operation in which the same construction is used. This is the first case on record where trouble has resulted due to the use of the core bolts, and it is very remarkable that it should have occurred on two machines in such rapid succession, though the fact that they are duplicates and built by the same workmen may explain this.

The trouble was due to the fact that a peculiar combination of conditions resulted in the bolt having a frequency equal to that of the machine, and vibration once having been set up, the insulation on the bolts was more or less rapidly disintegrated.

While the Metropolitan-Vickers Company assumes full responsibility for the trouble which has occurred, the following points might be emphasized:

1. The insulation on the windings of the machines has been in no way responsible for the breakdowns.

2. The voltage between the bolts and core was approximately 100, and while the damage was due finally to the breakdown of the insulation on the bolt, the cause of the breakdown was purely mechanical.

3. The construction which was responsible for the trouble is not a new or experimental one, the breakdowns being due to a particular combination of conditions the existence of which could not reasonably have been anticipated.

We have received a bulletin published by the Neptunus Ship Supply Co., Inc., describing and illustrating the Erfmann boiler water controller. This little apparatus has been devised to provide a means of determining the amount of soda water necessary to be fed to the boiler with the feed water in order to neutralize the scale-forming and acid-making constituents. It consists of a small case with two graduated vessels, and two bottles containing the necessary chemicals to produce the reaction from the sample of feed water taken. Ample directions are given for testing the boiler water, which is drawn off into one of the graduated vessels, and the amount of soda necessary is read direct from a graduated scale on the testing vessel. The firm's address is 73 Front street, New York City.

A 1,000,000 HORSE-POWER HYDRO DEVELOPMENT

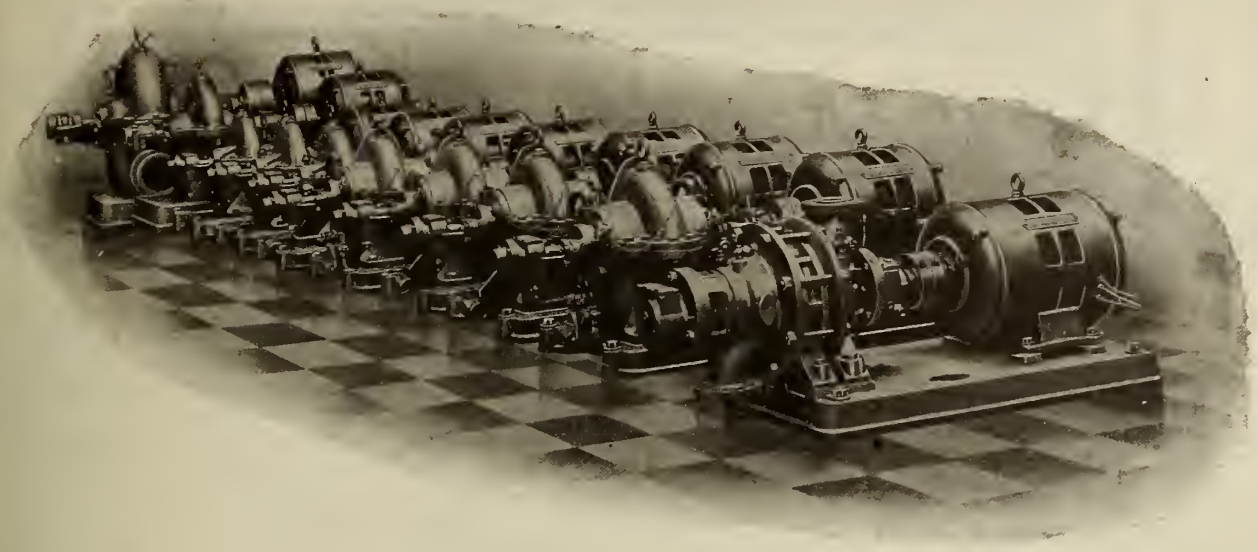
(Continued from page 29)

care should be taken that they are developed the right way, and that no gross monumental blunder be made at that time.

This reminds me of a story told me by a minister in Toronto some forty-five years ago, which illustrated his point, that if one could not do a thing in the right way, it would often be better not to do it at all. He did this by citing a case of a man who fell off the Yonge street dock the preceding week. A spectator rushed up and down yelling "Save him! Save him! Why doesn't somebody save him!" And as nobody seemed to be doing anything, he thought that he would have to do it himself. So he seized a log of wood and threw it to the man in the water, thereby knocking his brains out.

This work can be done so as to pay enormous taxes in addition to the great benefits of cheap power, transportation, etc., or it can be done for great outlays of public money which will never be returned.

Which shall it be?



Allen "British-built" Pumps

Specified Wherever Continuous Power Supply Is Required

The illustration shows Allen Direct-Connected Centrifugal Pumps supplied to a large Canadian power company. Allen Pumps are in satisfactory use all over the world. More than one hundred and fifty British battleships have Allen pumps installed; dockyards and power houses throughout the world have proved their value.

They withstand overloading and the emergencies that good pumps must meet. They are especially recommended for service far removed from the repair shop.

Simplicity is their principal feature. When required they are easily dismantled. Few moving parts mean longer life and freedom from repairs.

Allen Pumps may be had for direct coupling or belt drive, reversible and non-reversible.

The Operators' Point of View

DIESEL V. SEMI-DIESEL

AS an old subscriber of more than ten years' standing I would like to make a few remarks regarding an article in the Power House issue of February 20, 1921, by F. A. McLean, of the Canadian Ingersoll Rand Co., and in which I was very much interested, as I am a Diesel oil engineer myself, and I beg to differ with him on some points.

In paragraph two of the article he mentions the poor flexibility, in starting and stopping, of a Diesel engine. This point is not quite clear to me, as a Diesel engine can be started from cold, and be put on full load within two minutes after entering the engine room, and can be stopped by closing off fuel and injection air.

Mr. McLean also makes the same mistake as many other engineers in regard to the high compression pressures and temperatures of the Diesel engine cycle. That is, that they are much higher than those prevailing in oil and gas engines of the low compression type, and with the consequent inability of the metals to withstand the severe service.

Now this is incorrect. The compression pressure, it is true, is higher, viz., 475 to 500 lbs. per sq. inch, with corresponding temperatures of 950° to 1,000° F. scale, and I may say these are about the maximum, whereas the temperature of the exhaust of gas engines is often considerably more than twice this working on the constant volume cycle.

Take the case of an engine working with a compression of 103.8 lbs. per sq. inch absolute and the explosive mixture to be one part gas to seven of air, and that the heat of the combustion of the gas is 640 B.T.U. per cu. foot. The temperature at the end of explosion would be 5.568° absolute or 5107° F, while the temperature of the exhaust would be about 2600° F. and the pressure at its maximum would reach 628.6 lbs. per sq. in. absolute, say, 614 lbs. gauge, and which would come on the piston almost as a dead blow, while the 475 to 500 lbs. per sq. in. would come gradual on the piston of a Diesel engine.

He also speaks of air injection pressures as if 1,000 lbs. per sq. in. were common. In actual working the pressures vary according to the load. No load, 520 lbs.; ¼ load, 570 lbs.; ½ load, 640 lbs.; ¾ load, 710 lbs.; full load to 10 per cent. overload, 780 to 920 lbs. per sq. in., and the compressor is part of the engine, and does not affect the B.H.P., but the engine would be 6 per cent. more efficient were it not necessary, and, in fact, some Diesel engines have solid injection instead of air.

Regarding the efficiency of heat engines. It is a well-known fact that the thermal efficiency in per cent. is dependent upon the heat or temperature used in the cycle. That is, temperature of reception less the temperature rejection divided by the total temperature of the working fluid, whether of steam in the steam engine or air in the gas or oil engine, whether the engine works with constant temperature cycle, constant volume cycle, or constant pressure cycle, the result is the same, $\frac{T_1 - T}{T_1} = E$ in per cent.

Take the case of a steam engine working between the limits of 150 lbs. pressure and 28 inches vacuum $\frac{819 - 563}{819}$ = 31.3 per cent. as the maximum thermal efficiency and about all we can expect from an engine of this type is from 50 to 55 per cent. of this, or, say, 17 per cent.

The formulae for gas and oil engines are more complicated, as there are your different temperatures during the cycle, but for the purpose of calculating the thermal efficiency we only need to use but two of them and can be calculated from the following formula:

$$\frac{T_4}{T_3} = \frac{(V_2)^{y-1}}{(V_1)} = \frac{T_1}{T_2}$$

and from which we deduce the following $E = 1 - \frac{T_4}{T_3}$ or $E = 1 - \frac{(V_2)^{y-1}}{(V_1)}$ and $\frac{V_1}{V_2}$ is called the compression or expansion ratio, and we will designate it by the letter R, so you will see that the thermal efficiency of constant volume cycle of a constant pressure cycle depends on the compression, expansion or volume ratio, which are the same, and the formula becomes $E = 1 - \frac{1}{R^{y-1}}$ for a mixture in a gas engine y = 1.37, and for air 1.405, say, 1.4 as used in four cycle Diesel and semi-Diesel engines.

Now the volume radio of the Ingersoll-Rand engine is $(\text{Log } 214.7 - \text{Log } 14.7) \div 1.4 = \log \frac{(V_2)}{(V_1)} = 6.8$ and the thermal efficiency becomes $1 - \frac{1}{6.8^{.4}} = 44$ per cent.

The compression ratio of the engine in my charge, working with an absolute pressure of 476 per sq. in., is 12 for the value of R and $E = 1 - \frac{1}{12^{.4}} = 63$ per cent.

Taking the mechanical efficiency as .55 per cent. of the thermal gives the Diesel a mechanical efficiency of 34.5 per cent. and the Ingersoll-Rand engines as 24.2 per cent.

Let us now examine the maximum temperatures of the Diesel and Ingersoll-Rand respectively. Air at 60° F. 521 abs

$T_2 = T_1 \times 12.^4 = 521 \times 12.^4 = 1408$ F. abs. 947° F. scale and as engine works on constant pressure cycle, volume increasing as the heat is supplied, there can not be much increase in temperature though expert opinion is that there is a slight increase.

The final temperature of a constant volume engine is the sum of heat of compression and heat of combustion, and is a complicated formula, but as the compression pressure and final explosion pressure are given and the medium is heated at constant volume, it can be calculated from the following:

$$T = \frac{521 \times 6.8^{.4} = 439.7}{214.7} = 2000^{\circ} \text{ app.}$$

abs. temp. or 1539° F. scale, or about 60 per cent. higher than that of the Diesel engine.

There are other points that I would like to take up, but feel this article is already too long. My intention has been to give some figures to correct the prevalent opinion among engineers that there are high maximum pressures and temperatures in the cylinder of a Diesel oil engine, and to show that though the compression pressures of gas and oil engines are lower the maximum pressures and temperatures are much higher than that of the Diesel cycle.—David Rowlands, Canora, Sask.

SUCCESSFUL STEAM TURBINE OPERATION*

By F. L. Ray

So much has been contributed to the power plant press by operating men on the subject of this paper that it is almost impossible to add anything new on how to get successful operation of turbines. However, a restatement of some essentials will not, we trust, be time wasted, for to be forewarned is to be saved from disaster, and the operator who sticks close to the beaten path laid down by experience will be following a never-erring guide that will lead to success.

The super-turbine units have introduced problems peculiar to their large size, but, generally speaking, the same set of rules will supply from 600 to 60,000 horsepower, the difference being in the use of higher pressure and higher temperature of steam.

There are just three main essentials to turbine operating, and are in order as given—safety, service and economy, and under these heads may be laid down many rules.

Safety.—Of first importance are the safety devices to prevent the over-speeding of turbines, which devices operate to shut off steam if speed reaches a predetermined maximum, usually about 10 per cent. above normal. These devices should be tested as often as machines are shut down by speeding up until the automatic valve trips, for failure of this device has caused many serious troubles that could have been prevented. The operator should exercise eternal vigilance over these safety devices, for this is the price that must be paid for safety.

Service.—Of the next importance to safety of operation there comes service, for in the last analysis this is the prime object of the operation of the turbine, to furnish power for a thousand uses and to supply that power at a stated time and in quantity as contracted for. There must not be any sacrifice of safety to get service, but there may be to get safety and service, a sacrifice of economy.

Economy.—The larger the unit the better the economy, but to get maximum economy from any size turbine it must be operated as near as possible at the load specified by the builder for certain condition of steam pressure temperature and vacuum. Any change from the specifications as to steam pressure, superheat or vacuum will mean a loss.

If you will follow these few simple rules, as given below, your turbine operation will be more successful:

1. Test speed limit device every time turbine is shut down. If device does not work so that throttle is closed within the prescribed limits, then correct the trouble at once.

2. Make sure that automatic vacuum breaking device is always in working order. Do not fail to have a hand-operated vacuum breaker convenient to throttle valve so that if the other device fails then the vacuum can be broken quickly by hand device.

3. Test governor on turbine for control by opening throttle after load is off, and noting speed. Governor should not permit an increase of more than 2 per cent. above normal with full vacuum and steam pressure on. If this test is made once each month, it should suffice.

4. Do not fail to keep governor on drive from circulating pump in good order, for if for any reason the pump should lose its water there would be a wreck due to over-speeding.

5. Lubrication must not be neglected. Use a good grade of turbine oil and provide a filtering system so that all oil can be changed twice each month.

6. Provide clean, pure soft water for sealing glands so that there will be no liming of these parts to cause trouble. Take the turbine apart and thoroughly inspect and clean at least once each year.

7. If possible, always have a spare unit ready to start at a moment's notice. If the spare unit must be down for repair, then every effort must be exerted to get it back into service again, for the next minute you may need it, and without it the service would be interrupted.

8. Plan your repairs to the spare unit, so that if another unit should fail you would have the minimum of interruption to service. Some times these can best be made after midnight or on Sunday when the demand for power is lightest.

9. Take no chances with equipment, if through its failure you should cause an interruption to the service.

10. Regular systematic inspection of apparatus will prevent many an accident and be a safety first move as well as insuring against interruption to service.

11. Do not wait for something to happen, but plan ahead so that your repair work will always be well ahead of the breakdown and thus prevent what every successful operator abhors, an interruption to service.

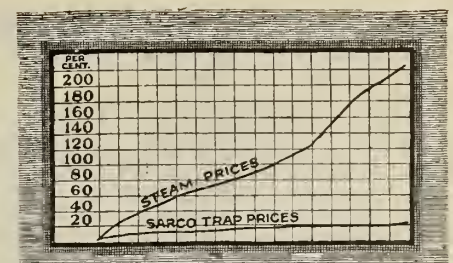
A turbine will be operated economically if it is successfully operated, for to successfully operate it, it must be operated under conditions conducive to economy. It must be kept in good order, the steam pressure must be just right, the temperature of steam must be neither too high nor too low, the vacuum must be as close to the maximum prescribed as possible at all times.

Therefore, successful turbine operation depends on safety first methods being followed closely, which will give service of the first order, with maximum economy.

---

*Read before Indiana No. 16, N.A.S.E.

F. W. Evans, manager of the Toronto branch of the Canadian Fairbanks-Morse Company, has returned to the city after a six weeks' vacation. Mr. Evans' health is much improved as a result of the trip.



Stop Waste at the Coal-Pile

Steam costs 200% more than it did five years ago, but Steam Trap SARCO prices have not increased more than 20%. The relation between cost and saving in dollars and cents is so much greater now than before the war that you cannot afford to leave lines untrapped or badly trapped.

Coal to-day is so high—and frequently so hard to get—that every shovelful counts. It will pay, and pay big, to check up on your steam line and see where coal is being wasted and money being lost through insufficient trapping.

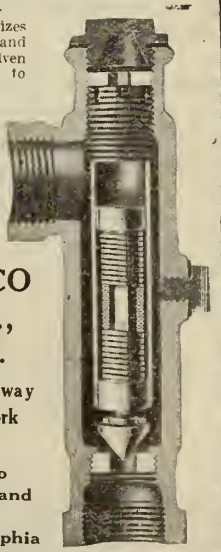
You can put in **three** Steam Trap Sarcos—**stop the loss at three different points**—for the cost of just **one** old-style trap.

The Sarco closes promptly and positively prevents all loss of live steam. And it returns condensate to the hot well while still hot.

Sarco is so small and compact that it takes little more room than an ordinary elbow—can be installed at steam-wasting points where the bulkiness of old-style traps would make them out of the question. No platform, pit or supports needed.

We are ready to let Sarco demonstrate its superiority and economy right in your own plant by sending you one on 30 days' trial without a cent in advance. If for any reason whatever you aren't satisfied with its performance, if it doesn't prove that it quickly pays for itself through the coal it saves, then you can return it and it won't cost you one cent.

Made in sizes ⅜" to 3", and for any given pressure up to 200 lbs.



Booklet No. J-12 and full particulars about our free trial offer on request.

Steam trap SARCO

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Question:—What is meant by the factor of evaporation? What has it to do with the quantity of water in the boiler? With steam at 100-lb. gauge and feed water at temperature of 160 degrees, what is the factor of evaporation?

2. In a flat surface supported by stays what is the allowable pressure when the plate is 7/16 thick and the pitch of stays is 9 x 9 inches? What is the difference in the diameter of direct and diagonal stays?

3. What would be the strengths of three different joints, single riveted lap, double riveted lap, and triple riveted butt strap, when the plate is 7/16ths, the rivets 7/8 and the pitch 2.708 inches?

Answer.—Your first question is on the factor of evaporation, and has nothing to do with the quantity of water in the boiler, but with the amount of heat necessary to heat 1 lb. of water. For instance, to turn 1 lb. of water at 212° into steam at 212° requires 966 B.T.U. Then if your feed water is 160° and steam at 100 lbs., the total heat required will be the difference between 160° and the temperature of steam at 100 lbs. gauge, plus the latent heat. The temperature is 337° and the latent heat is 880.4, so the total heat is 1,217 B.T.U. The feed water is 160, so we have 1,217 — 160 = 1,057 B.T.U. per lb. of water changed to steam. This is more than 966, and the factor of evaporation is 1,057 ÷ 966 = 1.094. Now this means that there is so much less water evaporated per unit of heat. If the boiler is rated at 100 H.P. this means it can evaporate 3,450 lbs. water from 212° to steam at 212° per hour. Now if it evaporates the same weight of water from 160° to steam at 337° it is performing more than 100 H.P. It will be 100 × 1,094 or 1.094 H.P. On the other hand, if it is to keep to 100 H.P. it would only have to evaporate $\frac{34.50}{1.094} = 3153.5$ lbs. In the case of a boiler working at 100 lbs. gauge pressure and feed at 160° and evaporating 34.50 lbs. per hour, to get the equivalent evaporation from and at 212 we simply multiply the water evaporated by the factor of evaporation. To get the horse power we divide the product by 34.5.

The formula for the allowable pressure on a flat plate is

$$\frac{C\ (t + 1)^2}{S - 6}$$

where C is a constant, which varies under different conditions from 90 to 200; t is thickness of plates in 1/16, and S is surface supported. Putting in your figures we get, calling C 90,

$$\frac{90\ (7 + 1)^2}{9 \times 9 - 6} = \frac{90 \times 64}{75} = 78.4$$

The pressure on the plate would then be 9 × 9 × 78.4 = 6350 lbs. If we allow 8000 lbs. per sq. in. on a direct stay the diameter will be

$$\sqrt{\frac{6350}{8000 \times .7854}} = 1.01, \text{ say,}$$

1 inch diameter.

The allowance on a diagonal stay is, according to its length, compared to the distance from the head to where the stay joins the shell. If the length of the stay is 42 and the distance from the head is 40, then the area of a diagonal stay would be to the area of a direct stay as 1.05 is to 1. The area of the direct stay is $\frac{6350}{8000}$, then the area of the diagonal stay will be $\frac{6350}{8000} \times 1.05$ and the diameter will be $\sqrt{\frac{6350 \times 1.05}{8000 \times .7854}}$ inches.

If the stress allowed on a direct stay is 8000 lbs., then on a diagonal it would be $\frac{8000}{1.05} = 7619.$

The joint you give would have percentage as follows:

Single Riveted Lap—Plate Strength $= \frac{P\ D}{P} \times 100 = \frac{2.708 - .875}{2.708} \times 100 = 67.68\%$

Rivet Strength— $= \frac{A \times n}{P \times t} = \frac{7 \times 7 \times .7854 \times 1 \times 16}{8 \times 8 \times 2.708 \times 7} = 50.7\%$

So strength of single riveted lap is 50.7 per cent.

For a double riveted lap the per cent. of plate would be the same, but the rivet strength would be just double. Thus:

$$\frac{A \times n}{p \times t} = \frac{7 \times 7 \times .7854 \times 2 \times 16}{8 \times 8 \times 2.708 \times 7} = 100.1\%$$

For a treble riveted butt strap join the pitch on the outside rows would b 5.416 inches. Thin plate strength woul be $\frac{5.416 - .875}{5.416} \times 100 = 83.8\%$.

The rivet strength would be $\frac{7 \times 7 \times .7854 \times 8 \times 16}{8 \times 8 \times 5.416 \times 7} \times 100 = 230\%$

The strength would, of course, be 83. per cent. In the formula the letter mean:

A = area of rivet;
n = No. of rivets in a pitch;
P = pitch of rivets;
d = diameter of rivet;
t = thickness of plate.

COMPOSITION OF FORCES

Question:—A B C is a triangle, o which the angle B is a right angle and th sides A C and B C are 60 inch and 1

Test Code for Evaporating Apparatus

Preliminary Draft of the Third of a Series of Nineteen Codes in Preparation by the A. S. M. E. Committee on Power Test Codes

IN 1918 the Power Test Committee of the A.S.M.E. was reorganized to revise and enlarge the Power Test Codes of the Society, published in 1915. The Committee is a large one, under the chairmanship of Fred R. Low, and under its direction are 19 individual committees of specialists who are drafting codes for the different classes of apparatus comprised in power-plant equipment. Below is reproduced the third of these codes to be completed, namely, the Test Code for Evaporating Apparatus.

This Committee will, of course, welcome suggestions for corrections or additions. These should be mailed before April 1 to the Chairman, care of The American Society of Mechanical Engineers.

Test Code for Evaporating Apparatus

Introduction

1. This Code of Tests of Evaporating Apparatus is intended primarily for apparatus heated by steam, such as vacuum pans, or single- and multiple-effect evaporators. The principal use for such evaporators is in the manufacture of alkali, salt, sugar, condensed milk, extracts from chemicals, and similar processes.

Objects

2. The objects of the test should be clearly defined before preparations are made. Some of the purposes for which tests of this character are made are to determine:

(a) The adaptability of the apparatus to the material to be concentrated;

(b) The most feasible and practicable method or methods of operation;

(c) The maximum and minimum range in capacity of the evaporator consistent with economical operation;

(d) The efficiency of the apparatus as a whole, and of its several elements;

(e) Relative capacity and efficiency of the apparatus compared with other apparatus doing similar work;

(f) The location of losses which may be minimized or eliminated by improved apparatus or better methods.

Measurements

3. The measurements involved in the testing of evaporating apparatus heated by steam will depend to some extent upon the object for which the test is conducted as defined in Par. 2 above. In general, these measurements will include the following:

(a) The general data relative to type of apparatus, and principal dimensions as defined in Table A, Items 7 to 20;

(b) The weight or volume of the liquor before and after each effect, and for the apparatus as a whole;

(c) The weight or volume of the steam to each effect and to the apparatus as a whole; also to any auxiliary apparatus;

(d) The pressure, temperature and quality of the steam to each effect; also to any auxiliary apparatus;

(e) The temperature, specific heat and specific gravity of the liquor before and after each effect, and before and after the unit as a whole;

(f) The weight or volume of water evaporated from the liquor;

(g) The weight or volume of condensing water used.

Instruments and Apparatus

4. The apparatus and instruments required for testing evaporating apparatus will include:

(a) Tanks and platform scales for weighing liquor and water, or calibrated tanks, or meters;

(b) Pressure and vacuum gauges;

(c) Thermometers;

(d) Calorimeters for determining the quality of steam;

(e) Hydrometers for determining the specific gravity of the liquors, and degree of concentration;

(f) Apparatus for analyzing the liquors;

(g) Barometer;

(h) Electrical instruments, including voltmeter, ammeter and wattmeter, if electrical measurements are necessary.

Note: For a full description of the use, calibration and accuracy of these instruments and pieces of apparatus, refer to the Code on Instruments and Apparatus.

Preparations

5. The General Instructions, Pars. 4 to 8, should be read, and preparations made accordingly, in so far as these instructions apply to the apparatus to be tested. Take the dimensions of the apparatus and the auxiliaries; note their physical condition; examine for leakages; select and install the testing appliances.

For the heating surface of the evaporating apparatus, measure the surface in contact with the steam, the liquor being in contact with the opposite side.

Where the apparatus is subject to vacuum, examine for leakage of air.

To test for air leaks close up and blank off the apparatus. Pump the air out of the apparatus, blank off vacuum pump, and see if air leaks are noted by decrease in vacuum. Small leaks difficult to find may usually be located by painting the joints and the surfaces, if porous, with a good quality of white lead.

Operating Conditions

6. Determine the operating conditions necessary to conform to the object of the test, and see that these conditions are maintained throughout the test.

Starting and Stopping

7. The pressures, temperatures, densities of liquors, and volumes of same within the evaporator should be the same at the beginning and at the end of the test. The test should be started at the beginning of a commercial cycle where such cycles exist in the operation of the evaporator, and after running the required number of hours it should be stopped at the beginning of the next succeeding cycle.

Duration

8. The duration of the test should depend upon the degree of accuracy demanded by the object for which the test is made. In no case should the duration be less than the regular commercial operating cycle. If the cycles are less than four hours in duration the test should cover at least three complete cycles, and the results of each cycle should substantially corroborate the other two. When the cycles are of four or more hours' duration the test should cover at least two complete cycles and these should be substantially corroborative. Should the operation be carried on in shifts the test should continue at least one calendar day of 24 hours. This length of time should be the duration when the supply of liquor or steam is irregular or intermittent, or when for any reason the regularity of the operation cannot be maintained.

Records

9. The data should be taken and recorded in the manner described in the General Instructions, Pars. 20 to 30. Half-hourly readings of the various instruments will be sufficient, except where there is considerable fluctuation in such readings, in which case more frequent readings must be taken in order to give good averages.

Uniformity of operation may be assisted by the plotting of a chart while the test is in progress, as pointed out in Par. 29 of General Instructions.

10. The data and results should be tabulated in accordance with the form shown in Table A, forming part of this Code, adding items not provided for and omitting items not needed to conform to the object in view. Unless otherwise indicated, the items refer to the numerical averages of the readings which are recorded in the log.

The methods of calculating the results as tabulated, so far as not self evident, or not sufficiently indicated in

Republic
CO_2 RECORDERS

Don't Let Your Profits Go Up in Smoke

ESTIMATES show that, during the past year, over 150,000,000 tons of coal were wasted in Canada and the United States.

A great part of this enormous, almost criminal waste was due to improper combustion resulting from guess-work on the part of the operators.

What about **your** furnaces? Is part of your fuel money going up the smoke stack in useless gases and heat when it could, as easily, be converted into power? This can be simply and profitably remedied by installing a **Republic CO_2 Recorder.**

The Republic CO_2 Recorder is a simple, remarkably accurate apparatus for analyzing flue gases. It is complete in one case and has only two moving elements. As there are no glass parts or valves its accuracy is never affected by dust or ashes. It is always ready with clearly written records.

The entire construction of a Republic is almost unique. It is explained fully in our bulletin. Write for a copy.

Meters That SHOW Where Your Dollars Go

By using a Republic you know just what your furnace is doing NOW. The continuous flow of gas gives a charge directly from the furnace, not far behind it as in others. The analysis is recorded by a continuous line on the chart. The case complete measures 22 x 12 x 5 inches and the entire instrument weighs only 45 pounds.

the text for the items, are explained in the following section.

Calculation of Results

Liquor Levels (Table A, Item 28). The datum from which these levels are measured must be so given that it will be possible to calculate the hydrostatic head of the liquor in each effect.

Excess Boiling Degree (Table A, Item 34). The excess boiling degrees of the liquor in any effect is the difference between the boiling temperature of the liquor in that effect and the boiling temperature of water under the same pressure as that of the vapor in the effect.

11. Steam to Condenser (Table A, Item 52). This cannot be measured directly. If a surface condenser is used this item can be determined by measuring or weighing the condensed steam discharged from the condenser. If a jet condenser is used, Item 52 may be calculated from the weight of condensing water and the rise in temperature of the condensing water. The product of these two will give the heat transferred to the condensing water, and this heat divided by the heat in a pound of steam going to the condenser, reckoned from the temperature at which the condensing water leaves the condenser, will give the weight of steam going to condenser. The same item may be determined by taking the difference in weight between feed and discharge liquors in the last effect.

If any retained product is found in the steam to the condenser, this must be taken account of in calculating the weight of steam going to condenser.

12. Evaporation from Liquor (Table A, Item 53). This is the sum of the steam to the condenser (Item 52) and the condensed steam drained from the effects, except that from the first effect. [Total of Item 61, except (a).]

13. Liquor Entering (Table A, Item 56). The weight of liquor entering the first effect is the weight of the feed liquor.

In case it is possible to measure the liquor passing from one effect to the next by pitot tube, venturi tube, or other device, the weight of the liquor entering each effect may be calculated from such measurement, and the temperature and specific-gravity test of the measured liquor. If the condensate can be measured, the liquor entering any effect can be calculated by subtracting the weight of the condensate from the feed liquor, or the liquor entering the previous effect. If it is impossible to measure the liquor passing from one effect to the next, the sub-items of No. 56, except (a), had better be omitted, as the calculation of these items is very unsatisfactory.

14. Evaporation from Liquor in Individual Effects (Table A, Item 58). The satisfactory determination of the several sub-items of this number, except in the case of a vacuum pan, or single effect, depends upon the successful measurement, or calculation, of the liquor passing from one effect to the next. If the liquor can be measured the evaporation in each effect is determined by taking the difference in weight of the liquor entering and leaving that effect (Items 56 and 57), or by measuring the condensate directly.

15. Evaporation from Liquor from and at 212 Deg. Fahr. (Table A, Item 53). This is Item 68 ÷ 970.4.

16. Self-Evaporation (Table A, Item 59). Self-evaporation in any effect is determined as follows: Multiply the weight of the liquor entering that effect by the temperature drop between the boiling point in that effect and the boiling point in the preceding effect, and by the specific heat of the liquor. Divide this quantity by the latent heat of evaporation in the effect considered. The result is the weight of self-evaporation.

17. Heat Contained in Entering Liquor (Table A, Item 63). This is the pounds of feed liquor multiplied by the temperature above 32 deg. Fahr. of the feed liquor, and this product multiplied by the specific heat of the feed liquor.

18. Heat from Steam Supplied to Entire Apparatus (Table A, Item 64). This is the sum of the products of the pounds of steam, from Items 42, 43 and 44, multiplied respectively by the total heat, above 32 deg. Fahr., in a pound of steam of the pressures and qualities used.

19. Heat to Pumps (Table A, Item 65). This is the product of the pounds of steam to pumps, Item 44, by (the heat units in a pound of live steam to pumps minus the heat units in one pound of exhaust steam from pumps corrected for quality).

20. Heat Contained in Discharge Liquor (Table A, Item 66). This is the product of the pounds of discharge liquor (Item 51) by the temperature, above 32 deg. Fahr., of the discharge liquor, and this product multiplied by the specific heat of the discharge liquor.

21. Heat in Steam to Condenser (Table A, Item 67). If the quality of this steam can be obtained this item may be calculated from the weight of steam to condenser (Item 52) and the heat units in a pound of this steam; otherwise this item must be calculated from the heat absorbed by the condensing water; or, pounds of condensing water (Item 62) multiplied by rise in temperature of condensing water [Item 37 (b) —37 (a)]. To this must be added the heat in the condensate above 32 deg. Fahr.

22. Heat Contained in the Evaporation from Liquor (Table A, Item 68). This is the heat in the steam going to the condenser, plus the heat in the condensed steam drained from the effects (except that drained from the first effect: Item 67 + (Item 73 — Heat in condensed steam from first effect).

23. Heat Contained in Entrained Product (Table A, Item 69). From the analysis of the steam to the condenser (Item 92) the amount of entrained product is determined. The weight of this entrained product, multiplied by its temperature above 32 deg. Fahr., and this product, multiplied by the specific heat of the entrained product, will give the heat in such product escaping with steam to condenser.

24. Heat Supplied to Heaters (Table A, Item 70). This is the product of the pounds of live steam to heaters (Item 42) by the total heat above 32 deg. Fahr. in a pound of such live steam. To this must be added the heat supplied from exhaust steam, if any. This is the product of the pounds of exhaust steam to heaters (Item 47) by the total heat above 32 deg. Fahr. in a pound of such exhaust steam. In determining the heat in the steam the quality of the steam must be taken into account.

25. Heat in Water from Heaters (Table A, Item 71). This is the product of the pounds of water discharged from heaters (Item 60) by the temperature of such water above 32 deg. Fahr.

In case of more than one heater the heat will need to be calculated for each heater separately and the sum of the several quantities taken.

26. Heat Supplied to the Effects (Table A, Item 72). This is the product of the pounds of live steam to the effects (Item 43) by the total heat above 32 deg. Fahr. in a pound of such live steam. If exhaust steam is supplied to the effects its heat must be added to the above. Pounds of exhaust steam (Item 48) multiplied by the total heat above 32 deg. Fahr., in a pound of exhaust steam.

27. Heat in Condensed Steam Drained from Effects (Table A, Item 73). This is condensate taken from the steam space of an effect. In case of more than one effect this should be passed along to the next effect if possible, where its heat may, in part at least, be transferred to the liquor. This heat is the product of pounds of condensed steam [Item 57 (b)] multiplied by the temperature above 32 deg. Fahr. of such condensate. In case the apparatus has more than one effect the heat must be calculated for each effect separately, and the sum of the several quantities taken.

In case the condensed steam flows from the steam space of one effect to that of the next effect its temperature should be measured at point of leaving the last effect of the series. This temperature, in degrees above 32 deg. Fahr. multiplied by the pounds of condensed steam leaving the last effect will give the heat in the total condensed steam drained from the effects.

28. Heat Discharged from the Effects (Table A, Item 74). This is the sum of Items 66, 67, 68 and 73.

29. Apparent Heat-Transmission Coefficients. The apparent heat-transmission coefficient in any effect is obtained by dividing the total heat transmitted per hour in that effect by the heating surface in that effect, and by the ap

Extravagance Must Stop!

THE COPES Boiler Feed REGULATOR

is a vital organ in the system which draws the latent energy out of the coal pile and delivers it at the bus bar or the main drive shaft.

Without the Copes Boiler Feed Regulator none of the other organs can perform its function properly. Stokers, feed water heaters, water softeners, and the boilers themselves cannot do their best without proper feed water regulation. The legibility of steam and water flow records, pressure and temperature charts, all depend more or less on scientific feed water regulation.

For complete information about COPES BOILER FEED REGULATORS, ask for Bulletin D.

parent temperature drop. The apparent temperature drop is the difference between the temperature corresponding to the pressure of the heating steam and the temperature corresponding to the pressure in the vapor space of the effect.

The total heat transmitted in any effect is not the heat corresponding to the evaporation in that effect. It is less than this quantity by the heat in self-evaporation. The total heat transmitted is therefore determined by subtracting from the total evaporation (Item 58) the self-evaporation (Item 59), and multiplying this difference by the total heat (above the temperature of the vapor) in one pound of steam at the pressure and temperature of the vapor in the effect.

30. Corrected Heat-Transmission Coefficients (Table A, Item 82). Apparent heat-transmission coefficients, as outlined in Par. 29, may be corrected for

(a) Excess boiling degrees
(b) Hydrostatic head
(c) Both excess boiling degrees and hydrostatic head.

The report should clearly specify which of these corrections have been made.

If a coefficient is to be corrected for excess boiling degrees, the heat transmitted, as explained in Par. 29, is to be divided by the heating surface and by the temperature drop between the temperature corresponding to the pressure in the heating space and the actual boiling point of the surface liquor in the effect in question.

If a coefficient is to be corrected for hydrostatic head the total heat transmitted, as explained in Par. 29, is to be divided by the heating surface and by the temperature difference between temperature corresponding to the pressure in the heating space and the boiling point of the liquor at the mid-point of the hydrostatic head. This last temperature is to correspond to a pressure equal to the pressure of the vapor space plus a pressure due to a column of liquor equal to one-half the hydrostatic head.

Evaporative Ratio and Efficiency of Individual Effects

31. Overall Thermal Efficiency of the Entire Equipment (Table A, Item 75). This is the ratio of the heat contained in the total evaporation from liquor, to the heat from steam supplied to entire apparatus. Item 68 divided by Item 64, and the quotient multiplied by 100 to give percentage.

32. Thermal Efficiency of the Effects (Table A, Item 76). This is the ratio of the heat contained in the evaporation from liquor to the heat supplied to the effects. Item 68 divided by Item 72, and the quotient multiplied by 100 to give percentage.

If the evaporation from liquor in each effect [Item 58 (b)] is calculated, then these figures, with those of Item 61 (b), may be used to check the above quantity of heat in steam evaporated from liquor, or to figure the efficiency of each effect, and of all effects.

33. Thermal Efficiency of Heaters (Table A, Item 77). This is the ratio of the heat put into the liquor in its passage through the heaters to the heat supplied to the heaters.

Item 50 multiplied by [Item 33 (a) — Item 32 (a)] and by the specific heat of the feed liquor.

The above product divided by Item 70, and this quotient multiplied by 100, will give percentage.

Economy

34. Evaporation Per Pound of Total Steam Used (Table A, Item 83). This is Item 51 ÷ Item 45.

35. Evaporation from and at 212 Deg. Fahr. Per Pound of Total Steam Used (Table A, Item 85). This is Item 54 ÷ Item 45.

TABLE A—DATA AND RESULTS OF EVAPORATING APPARATUS TEST.
(A.S.M.E. Code of 1920)

General Information.

(1) Date of test .....
(2) Kind of apparatus under test (vacuum pan, multiple-effect evaporator, etc.) .....
(3) Location .....
(4) Owner .....
(5) Builder of apparatus .....
(6) Test conducted by .....

Description, Dimensions, etc.

(7) Type of apparatus .....
(8) Dimensions of shells .....
(9) Material of tubes and tube sheets .....
(10) Number of tubes in each effect .....
{ Length.....
{ Diameter.....
(11) Heating surface in each effect .....sq. ft.
(12) Number and type of liquor heaters .....
(13) Number of tubes in each heater .....
{ Length.....
{ Diameter.....
(14) Heating surface in each heater .....sq. ft.
(15) Liquor heating surface in each heater.sq. ft.
(16) Type and make of condenser equipment....
(17) Condensing surface .....sq. ft.
(18) Type and dimensions of vacuum and circulating pumps .....
(19) Kind of liquor concentrated .....
(20) Characteristics of liquor concentrated.....

Test Results.

(21) Duration of test .....hr.

Average Pressures and Temperatures—

(22) Steam pressure by gage .....lbs. per sq. in.
(23) Barometric pressure .....in. of mercury
(24) Absolute steam pressure.....lb. per sq. in.
(25) Pressure in exhaust-steam line from pumps .....lb. per sq. in.
(26) Pressure or vacuum:—
(a) 1st effect ....lb. pressure....in. vacuum
(b) 2nd effect ....lb. pressure....in. vacuum
(c) 3rd effect ....lb. pressure....in. vacuum
(d) 4th effect ....lb. pressure....in. vacuum
(e) 5th effect ....lb. pressure....in. vacuum
(f) 6th effect ....lb. pressure....in. vacuum
(27) Vacuum in the condenser.....in of mercury
(a) Corresponding absolute pressure .....lb. per sq. in.
(28) Liquor levels:—
(a) In 1st effect .....inches
(b) In 2nd effect .....inches
(c) In 3rd effect .....inches
(d) In 4th effect .....inches
(e) In 5th effect .....inches
(f) In 6th effect .....inches
(29) Temperatures of saturated steam corresponding to the vapor pressure in:—
(a) 1st effect .....deg. fahr.
(b) 2nd effect .....deg. fahr.
(c) 3rd effect .....deg. fahr.
(d) 4th effect .....deg. fahr.
(e) 5th effect .....deg. fahr.
(f) 6th effect .....deg. fahr.
(30) Steam temperatures:—
(a) Superheated steam .....deg. fahr.
(b) Normal temperature of saturated steam .....deg. fahr.
(c) Temperature of exhaust steam deg. fahr.
(31) Temperature of liquor:—
(a) Entering 1st heater.....deg. fahr.
(b) Entering 2nd heater.....deg. fah
(c) Entering 3rd heater.....deg. fah
(d) Entering 4th heater.....deg. fah
(e) Entering 5th heater.....deg. fah
(f) Entering 6th heater.....deg. fah
(32) Temperature of liquor:—
(a) Entering 1st effect.....deg. fah
(b) Entering 2nd effect.....deg. fah
(c) Entering 3rd effect.....deg. fah
(d) Entering 4th effect.....deg. fah
(e) Entering 5th effect.....deg. fah
(f) Entering 6th effect.....deg. fah
(33) Temperature of liquor:—
(a) Leaving 1st effect.....deg. fah
(b) Leaving 2nd effect.....deg. fah
(c) Leaving 3rd effect.....deg. fah
(d) Leaving 4th effect.....deg. fah
(e) Leaving 5th effect.....deg. fah
(f) Leaving 6th effect.....deg. fah
(34) Excess boiling degrees of liquor:—
(a) In 1st effect .....deg. fa
(b) In 2nd effect .....deg fa
(c) In 3rd effect .....deg fa
(d) In 4th effect .....deg. fa
(e) In 5th effect .....deg. fa
(f) In 6th effect .....deg. fa
(35) Temperatures of condensed steam discharged:—
(a) From 1st heater .....deg. fa.
(b) From 2nd heater .....deg. fa
(c) From 3rd heater .....deg. fa
(d) From 4th heater .....deg. fa.
(e) From 5th heater .....deg. fa
(f) From 6th heater .....deg. fa.
(36) Temperatures of condensed steam.—
(a) Drained from 1st effect.....deg. fa.
(b) Drained from 2nd effect.....deg. fa
(c) Drained from 3rd effect.....deg. fa
(d) Drained from 4th effect.....deg. fa
(e) Drained from 5th effect.....deg. fa
(f) Drained from 6th effect.....deg. fa
(37) Temperature of condensing water:—
(a) Entering condenser .....deg. fa.
(b) Leaving condenser .....deg. fa
(38) Temperature of air in evaporating room .....deg. fa
(39) State of weather:—
(a) Temperature of external air...deg. fa
(b) Relative humidity of external air .....per cent.

(To be continued)

QUESTIONS AND ANSWERS

(Continued)

Answer:—What our correspondent s after is, we think, an explanation of e resolution of forces. His question s stated in a rather peculiar manner, s there is no need to suppose the prese e of a spring balance. A force of 1 lbs. acts along the line A B. Now force would be one of the compone s of the resultant force, which is expres in magnitude and direction by the di onal of the parallelogram of for Any two forces acting through a co mon point, can be resolved into a sin force acting through the same poin the following manner. Let the lines Y and OX represent in magnitude d direction two forces acting through t point O. If we complete the parall gram as shown, the diagonal will re sent in direction and magnitude the e sultant of the two forces. Similarl we have a single force we can res it into two forces at right angles to e other. In the case given we can ass the two forces to be acting along B and AB through a common point A. h force acting on the BC will be equ t AB sine A, which is taking the meas ments given, 31 x 15 60, while the f c acting on AC is equal to AB cos A, which is 31 .968. These give us respectively 7.75 and 32.07 lbs. The compon t forces are 7.75 and 31, while the re tant force is 32.02.

For Furnace Linings and Baffles

That are easy to install—air and gas tight, that cannot crack, chip, spawl or peel off—no separate fire brick, no mortar joints and not affected by expansion and contraction use

BETSON'S REGD. TRADE MARK PLASTIC FIRE BRICK PAT. OFF.

a plastic, unbaked fire brick material—made of the best fire clays and refractories—proportioned and mixed to withstand all strain, heat, gas and chemical action to which it may be subjected by the hardest usage. It outwears all other boiler furnace linings.

Write for informing pamphlet.

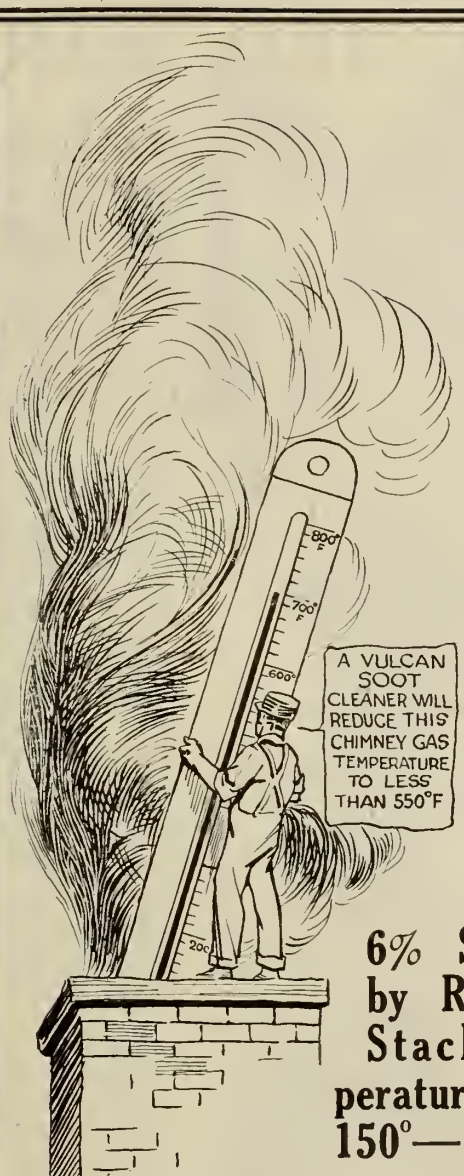
NEW AND USED

POWER EQUIPMENT



6% Saved by Reducing Stack Temperature 150°—

A certain plant found, by pyrometer test, that it had a stack temperature of 700 degrees. Obviously, it was losing a considerable amount of the heat value of the coal burned.

About that time, it installed Vulcan Soot Cleaners on its five boilers. Almost immediately the stack temperature dropped to less than 550 degrees—a clean drop of 150 degrees.

Analysis showed the coal to have a heat value of 12,000 B.T.U. With this as a basis, it was determined that Vulcan Soot Cleaners were responsible for a fuel saving of 6 per cent.

If your stack temperature is too high, it will pay you to look into Vulcan Cleaners as a means of lowering your present costs.

"Spending $796 to Earn $1017.40"

Let us send you our folder giving a mathematical demonstration of the actual dividend-producing value of Vulcan Soot Cleaners in dollars-and-cents. Sent free upon request.

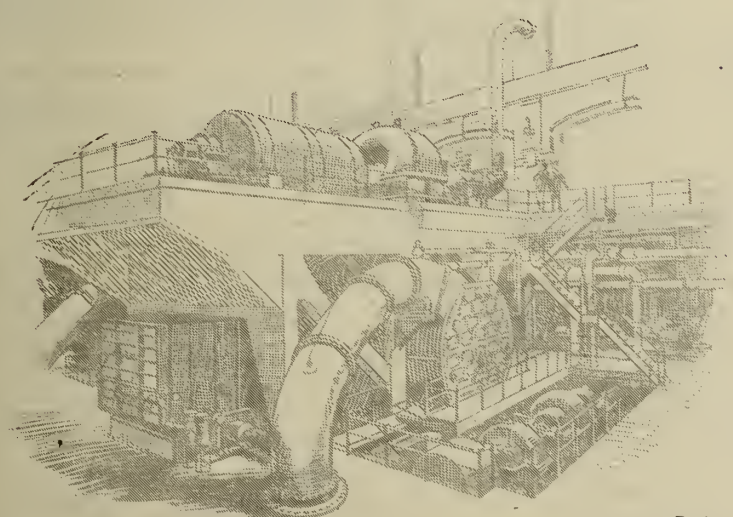
Why Engineers Consult Worthington on Condenser Questions

THE largest and most important power plants in the United States—plants that have established and are holding records for economical power production—are equipped with Worthington condensing apparatus.

Worthington was the pioneer in this branch of the power field, and for more than forty years has led the way in designing and constructing condensing apparatus of every type.

This accumulated experience enables Worthington to offer recommendations on condensing equipment to meet all conditions of service. The fact that Worthington builds all types of condensers guarantees impartial recommendations.

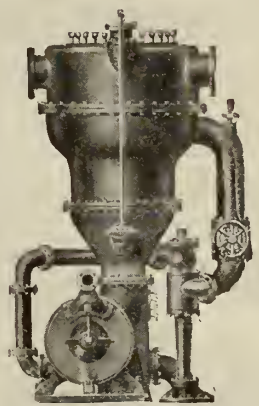
WORTHINGTON PUMP AND MACHINERY CORPORATION
Executive Offices: 115 Broadway, New York City
Branch Offices in 24 Large Cities



B-40

Spirojector Condenser

Counter Current Barometric Condenser



Parallel Flow Centrifugal Jet Condenser

Surface Condenser

Worthington builds surface condensers of two general types—standard and the so-called waterworks type. Both are equally economical. They produce a net saving in the operation of the plant in which they are installed, sufficient to earn their first cost in a very short operating period. Working conditions determine the type of condenser to be used, and Worthington engineers make their recommendations accordingly.

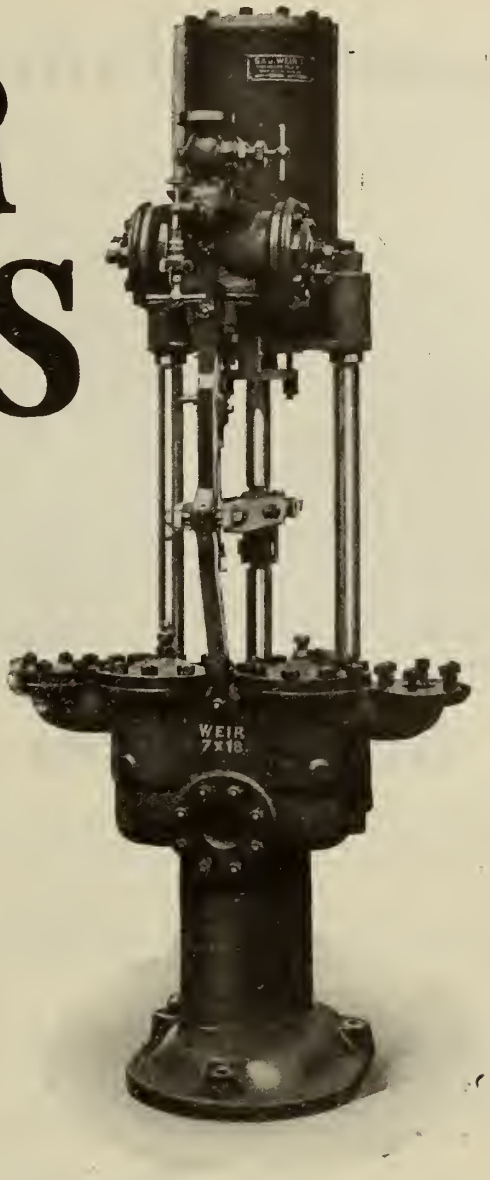
WEIR PUMPS

Slow — Steady Powerful



THE slow, powerful strokes of Weir Pumps maintain a constant, steady pressure month in and month out with no fear of a breakdown. A slow stroke means evener pumping and far longer life.

The accurate design and high-grade materials of all Weir Products have gained them a reputation for consistently meritorious operation throughout the entire world.

As large stocks of standard Weir Products and parts are always carried in stock and in the course of construction by us, we are in an exceptionally favorable position to meet demands for urgent deliveries. Moreover, the well-known Weir system of interchangeable parts greatly facilitates overhauling and renewal.

To serve our clients efficiently, satisfactorily and to the full extent of our ability—this is the Weir idea of service.

We offer to our customers the entire resources of our organization — research, designing, manufacturing and operating. We place at their disposal the experience, the data and the results of our thirty years' concentration upon specific lines.

PEACOCK BROTHERS, LIMITED, MONTREAL

TORONTO VANCOUVER

George Ham says "Good-Bye"

A STRIKING and affectionate farewell is bade by Col. George H. Ham in the March 15th issue of MACLEAN'S MAGAZINE, to his thousands of friends, as well as to other readers who may know him only by hearsay, who have been following his reminiscences in Canada's National Magazine since last August.

"The Curtain is Rolled Down, for seventy-three years makes a long act," says George. "Recalling three score and ten of these years has been a pleasant though difficult task; thirty-three of them have been spent in the service of the C.P.R., and one cannot but realize that the corridors of the Company's office will not long be trodden by the older ones of this generation and that some of us perhaps will soon not even be a memory."

"There Were Giants in Those Days"

The concluding instalment of this remarkable, all-Canadian feature, is the biggest and best of the lot—and here is the proof: There are seven full magazine pages, chock full of stories of those amazing days when the C.P.R. was conceived and constructed; human, hitherto unpublished details of the lives and careers of those three veteran founders, and, later, presidents of our first transcontinental: **Lord Mount Stephen**, the late **Sir William Van Horne**, and **Baron Shaughnessy, K.C.V.O.** And funny stories! Well, just read about Baron Shaughnessy's racing experiences; the pranks George Ham and William Stitt used to play on each other; Fred Cook's "German Band," and countless other incidents that could only be retained in such a mind—and heart—as that possessed by Canada's grand old raconteur.

Big Features of Fiction and Fact

"Personality, Plus"—By Guy Morton.
A fascinating story about an advertising agency man who put across a trick to close a contract—and then gave the whole game away.

"Lenix Fools the Jinx"—By Archie P. McKishnie.
Another of those deliciously droll Lenix Ballister negro stories, in which more than the usual number of comic and absurd scenes are depicted.

"Pawned"—By Frank L. Packard.
The third instalment of this masterful serial goes a long way to show how the triple regeneration is going to be effected.

"Broadway to Brussels"—By C. C. Jenkins.
The story of the rise of J. H. Gundy, a shy youngster, who developed into one of Canada's most brilliant orators and a leading financier.

"Little Bundles of Pluck"—By Agnes C. Laut.
In this, Miss Laut tells with graphic pen the story of some of the war brides who are making good out on the lonely prairies, where they and their husbands have been located by the S.S.B.

"A Woman Would Know ——"—By Charles G. Booth.
This whole gripping story centres around the possession of a wee bundle of humanity, cursed with a dope-fiend father. There is plenty of love interest, too.

"Those Who Stood in Darkness"—By J. L. Rutledge
A symposium giving the opinions of a number of Ministers of various denominations on some of the doubts which have arisen in this war aftermath, in the minds of many Christians—and others. An Easter Message.

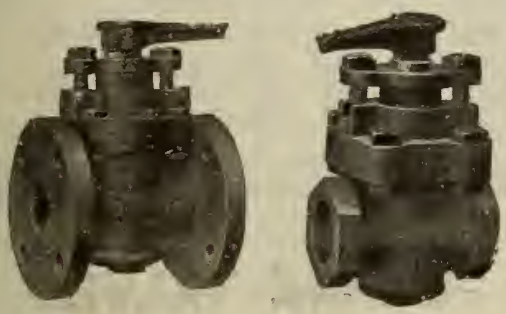
HOMESTEAD
QUARTER TURN VALVES



Quick Action

A quarter turn, and the Homestead is opened to a straight, unobstructed flow; a quarter turn back and it is closed absolutely tight by a patented wedging cam that automatically forces the plug downward.

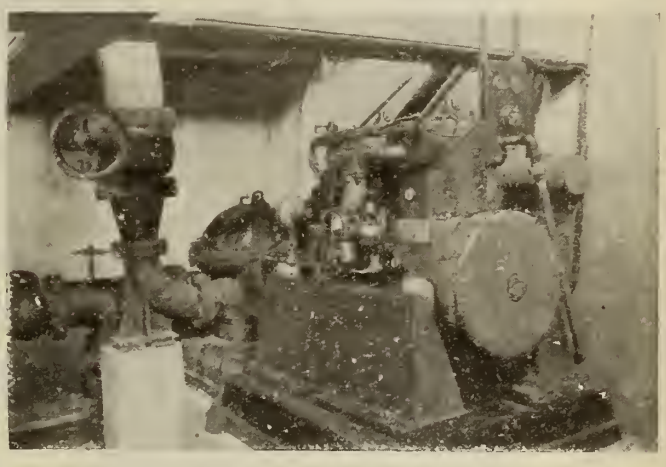
Use them for your blow-offs, throttles, tank valves and every other service where the duty is exceptionally severe and frequent opening and closing is required.

Homestead Valve Mfg. Co.
PITTSBURGH, PA.
Works : Homestead, Pa.

Of what use are two electrically driven pumps in emergency when power is off? Why not equip one with a high duty

Sterling
THE ENGINE of REFINEMENT
For the finest boats that float

gasoline engine with electric starter—as many others are doing?



Four cylinder, 100-H.P. Sterling, direct connected to Dayton-Dowd 1250-G.P.M. pump, speed 1350-R.P.M., at Sorel, Que., for stand-by service as a protection against breakdown.

Catalog on request.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts. It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Write for our catalogue.

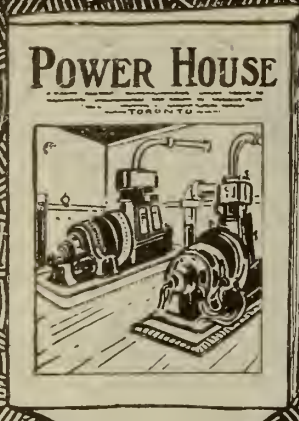
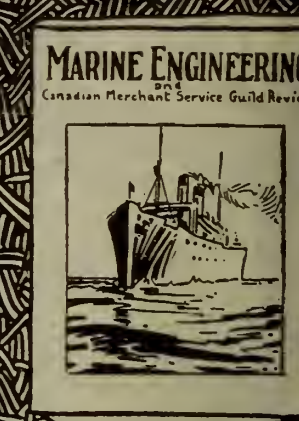
Instructive Advertisements

"I think the advertisements are good and I read them all the time. If it were not for the ads. I would not be able to keep up-to-date on new equipment. It is the only way we learn about anything new, as circulars are mostly kept in the offices," writes a Hamilton reader.

Double Moral—Read the Advertisements. Use POWER HOUSE *for Advertising.*





The Influential Four

For Self-Promotion and Sales Promotion Use These Publications

CANADIAN MACHINERY
Weekly—$4.00 per year.
Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

POWER HOUSE
Twice a month—$2.00 per year.
Serves the power plant engineer—Steam, Electric Refrigeration, Hydraulic.

CANADIAN FOUNDRYMAN
Monthly—$2.00 per year.
A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING
Monthly—$2.00 per year.
Interprets marine engineering in its broad sense, serving the ship builders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate).

Sturtevant

(REG·U·S·PAT·OFF·)

Type "D" General-Purpose Heavy-Duty Direct Current Motor

Practical Tests Have Proven Its Merits

until now, after 30 years' development, it stands foremost as an ideal individual or group driver.

Perfect mechanism and design, choice materials and only skilled workmanship are incorporated in them to give the user reliable service and greater power economy.

For driving lathes, boring mills, planers or grinders—in fact, any machine tool regardless of size—a Sturtevant Direct Current motor is especially adapted and successful. Very close regulation of speed is permitted, together with guaranteed sufficient overload and continuous full-load capacity.

All parts are very accessible, which is an important and advantageous feature when attention of any kind is required. The liberally designed bearings do not leak oil.

The 24 engineering offices we maintain are in all the principal cities. Consult any one of them about your motor requirements and they will gladly assist you. Also write to them for our bulletin 264U; if they can't supply you send to us direct at our Boston address.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract. Readers are requested to advise the publishers regarding any equipment that they are buying and that is not listed.

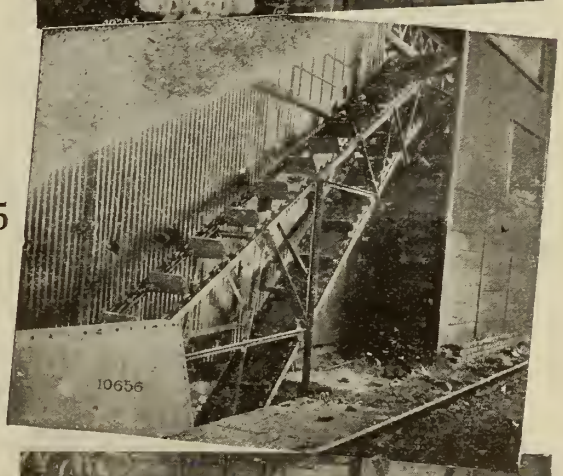
Typical Installation of

JEFFREY STANDARDIZED SCRAPER CONVEYERS

For Handling Coal In Boiler Houses

4



5

6

1—V-Bucket Conveyer, which acts as a scraper on the horizontal distributing coal to bunkers.

2—Single Strand Scraper Conveyer over storage bins in gas producer plant of a large glass factory. Scrapers are mounted on a single strand of "Flat and Round Link Chain."

3—Scraper Conveyer over bunker. Double Strand "Flat and Round Link" Chain is used.

4—Single Strand Detachable Chain Type of Scraper Conveyer over Bunker in electric plant.

5—Malleable Roller Chain with M-1 Attachments on a Scraper Conveyer handling coal from track hopper to storage bins in steel plant.

6—Scraper Conveyer consisting of Double Strands of "Vulcan" Chain with steel cross bars and scrapers, handling coal to bunkers.

Do your tests Measure up to Weston Standards?

Weston 310
Portable Wattmeter

The Weston Model 310 Portable Wattmeter is the ideal instrument for checking switchboard models or to accurately measure the load of any particular circuits.

This instrument and the kindred models—370 Ammeter and 341 Voltmeter—are suitable for use on either A.C. or D.C. circuits. The accuracy of this group is within ¼ of 1 per cent. of full scale value on D.C. circuits, and on A.C. circuits with any frequency up to 133 cycles in any wave form.

Our nearest house will gladly furnish detailed information on these or any other Weston instruments.

A Personal Message to Executives

Concerning

ELESCO SUPERHEATERS

If you are laying plans to put your plant in shape for the demands which will come on it when production is once more normal, you will be interested in the advantages of Superheated Steam.

Superheated steam reduces fuel bills from 10 to 20 per cent. It adds about 25 per cent. in boiler capacity to present installations at about one-fifth the cost of obtaining this increased capacity by installing new boilers.

It reduces the maintenance cost of your power plant equipment.

Your engineering department will know.

Bulletin NT-5 will be sent on request.

THE SUPERHEATER COMPANY, LIMITED

TRANSPORTATION BUILDING, MONTREAL
WORKS AT SHERBROOKE, QUEBEC

Designing Engineers and Manufacturers of ELESCO Steam Superheaters and Pipe Coils for all Purposes

Dart Unions are a Permanent Investment in a Pipe Line

The Bronze to Bronze feature eliminates all possibility of deterioration at the vital part. Bronze will not rust or corrode.

Iron Parts are Extra Strong. They will not stretch or pull apart under strain or heavy pressure.

Never scrap Dart Unions—use again—they're always efficient.

Improvements in Centrifugal Pumps

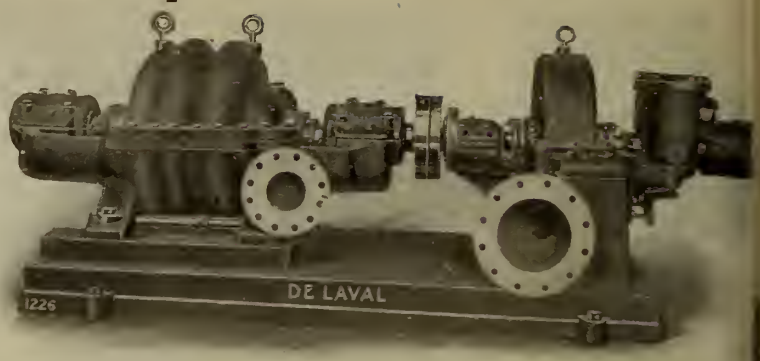
MOST of the features which distinguish the modern, efficient centrifugal pump from the old, inefficient pump limited to low heads were introduced by the De Laval Steam Turbine Co., and many of them are still peculiar to De Laval pumps.

The horizontally split casing with the suction and discharge openings in the bottom half, permitting the top half to be removed without breaking pipe joints or disturbing the alignment of the pump, was first introduced in a De Laval pump. It avoids the tedious, and sometimes almost impossible job of pulling parts out of a pump axially and it enables one to see that everything is put back as it should be.

Removable rings, upon both the impeller and upon the casing, where the two come close together, is another characteristic De Laval improvement, as also are the De Laval labyrinth rings by which leakage and loss of power are greatly reduced.

The De Laval pump first demonstrated that the highest efficiencies can be attained without the use of diffusion blades, and can be maintained much more successfully without than with diffusion blades.

The De Laval pump was one of the first in which the shaft was protected throughout against corrosion by water and wear by stuffing boxes by means of cast bronze sleeves or bushings. The De Laval pump also differs from many others in that a shaft of ample thickness to prevent rubbing under any conditions is employed.



The De Laval pump uses vertically split ring-oiled bearings which can be removed in halves.

In the De Laval pump the end balancing problem has been solved.

The cut shows a multi-stage pump of latest design driven by a De Laval velocity stage turbine.

Unique features of the De Laval pump, of the greatest importance to the purchaser, are:

Manufacture on a limit-gage, interchangeable basis, so that repairs or replacements ordered from the shop can be inserted by unskilled men, and

A policy of rigorous guarantees covering efficiency and other characteristics, coupled with the practice of testing each unit before it leaves the shop.

The De Laval engineering staff would be glad to give you the benefit of their experience in centrifugal pump engineering.

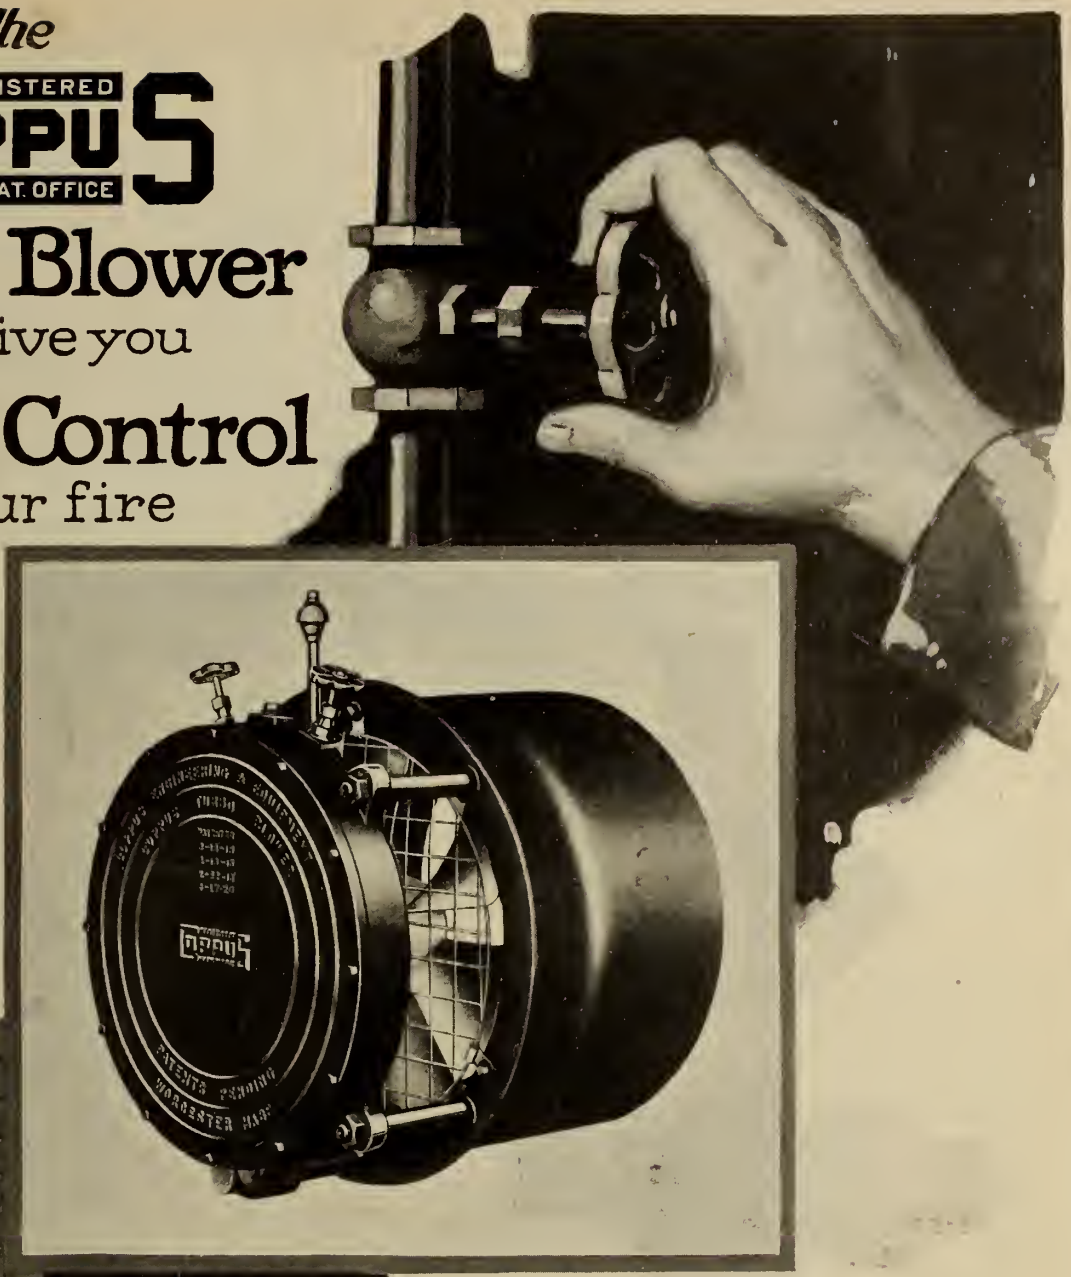
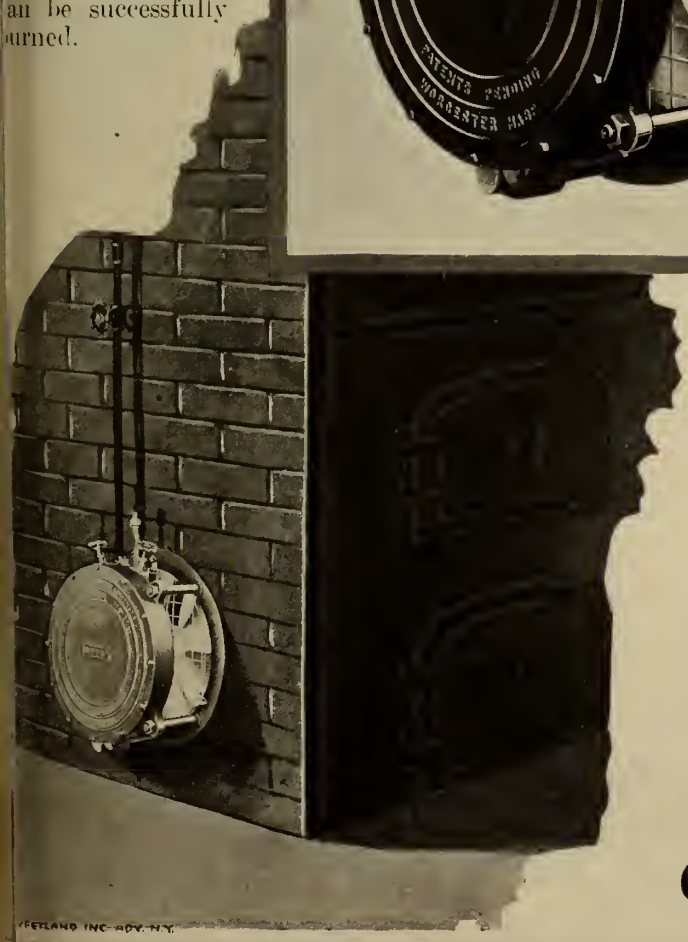
Turbo Blower will give you Valve-Control of your fire



ONCE unheard of — to-day standard practice in our most efficient boiler plants—*valve control of your fires.*

A turn of the valve gives an immediate "pick-up" of your fires. More steam in a hurry—and; mind you, the cheapest and poorest grades of coal can be successfully burned.



It is almost as easy to install a Coppus Turbo Blower under your boilers as it is to put an electric fan in your office. Merely cut a hole in the boiler setting—mason in the casing—make the simple steam connection, and it's done. Then you have valve-control of your fire—as easy as regulating the flame of a gas jet.

Coppus Turbo Blowers are standard equipment in efficiently operated boiler plants.

Our booklet contains interesting blower data. Ask for it.

Coppus Engineering & Equipment Co.

341 Park Ave., Worcester, Mass.

Morrison Steam Goods

"I know no way of judging the future but by the past," said Patrick Henry.

The modern power plant engineer paraphrases this by saying, "I know no way of judging the service which I shall secure from a line of steam specialties but by their past performance."

"Every installation is a demonstration of merit."

Look at the Inside

APPROVED
Trico Fuses are approved by the Underwriters Laboratories, Inc. Hydro-Electric Power Commission of Ontario, Canada.

TRICO
RED SEAL FUSE PLUG
(Powder-filled)

Light — Compact
100% Positive Indicator
WRITE FOR SAMPLES

THERE'S a reason why Trico Renewable Cartridge Fuses eliminate four-fifths of the blow-outs—save four-fifths of the time men and machines are idle for fuse renewals—cut the number and cost of renewal links required 80%.

Trico Fuses are powder-filled

Each Trico renewal element is a fuse in itself—a cartridge containing a fusible strip surrounded by an arc-choking powder that smothers the flame and absorbs the heat, absolutely preventing burning of the contact points. Because of this improved construction Trico Fuses carry starting and momentary overloads and still give adequate protection against prolonged overloads.

Send for descriptive literature. Or write us on your business letterhead for a test fuse of the capacity you use most. Then you can judge for yourself.

An exceptionally attractive proposition is now being offered to electrical supply jobbers and distributors in territories where we are not represented. Send for it to-day.

McEWEN HIGH-SPEED AUTOMATIC ENGINES

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country especially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

BRANTFORD, ONTARIO, CANADA

The Study of Bailey Charts Will Save You Many Dollars

Bailey Fluid Meters accurately indicate, record and integrate steam flow at all pressures and temperatures without constant recalibration or repairs.

They are a real necessity in determining the steam consumed by the main power generating units, the auxiliaries, the heating and drying system, special process work by the various factory departments and by outside users of steam.

Study Bailey Charts. The elimination of even slightly abnormal operating conditions may mean the saving of many dollars in coal and labor.

Write for bulletins.

TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Etched on 
Every Glass

TESTS OF HIGH PRESSURE GAUGE GLASS

Temperature—Not affected after 18 two-minute submersions in oil at 380 deg. F., then in water at 40 deg. F.

Erosion—No trace of erosion, and perfectly clear after live steam at 100 pounds pressure had passed through the glass for 96 hours.

Tensile Strength—Remained unbroken under hydraulic pressure of over 2,000 pounds per square inch for 2 minutes.

Service—Under continuous operating conditions with pressure of 225 pounds, performance equalled in every respect the best service ever obtained by any foreign glass.

DURABLA U.S.A. gauge glasses are now ready for distribution in all standard sizes and are sold under the DURABLA guarantee.

New Truths and Old Fallacies

Hardness of Alloys—*Continued*

We have referred several times to the compression test of alloys made by the American Society for Testing Materials, and we give the figures below:

FORMULA					Deformation of Cylinder 1¼" dia. x 2½" high at 70° Fahr.	
No.	Copper	Tin	Anti mony	Lead	At 1,000 lbs. in²	At 5,000 lbs. in²
1	4½	91	4½	..	0.0000	0.0010
2	3½	89	7½	..	0.0000	0.0015
3	8 1-3	83 1-3	8 1-3	..	0.0010	0.0045
4	3	75	12	10	0.0005	0.0025
5	2	65	15	18	0.0010	0.0030
6	1½	20	16	63½	0.0015	0.0050
7	..	10	15	75	0.0010	0.0050
8	..	5	15	80	0.0020	0.0090
9	..	5	10	85	0.0040	0.0120
10	..	2	15	83	0.0010	0.0100
11	..	..	15	85	0.0010	0.0100
12	..	..	10	90	0.0025	0.0170

In analyzing these figures it should be remembered that metals have no ultimate crushing strength, as they spread when the load goes beyond a certain point; also that tin base metals are more resilient than lead base metals and that the former will resume their original form, partially or altogether, when the pressure is removed, whereas a lead base metal will become permanently set under a comparatively light load, and the value of the above figures are somewhat dependent upon whether measurements were made before or after the load was removed. This thought was suggested by the apparently anomalous difference shown between formulas Nos. 1, 2 and 3. If formulas 1 and 2 did not resume their original form under the 1,000 lbs. pressure and partially resume it under 5,000 lbs., then all preconceived ideas are upset as to the value of copper as a hardener, as shown by comparison with the No. 3 formula, which contains a greater quantity of both copper and antimony.

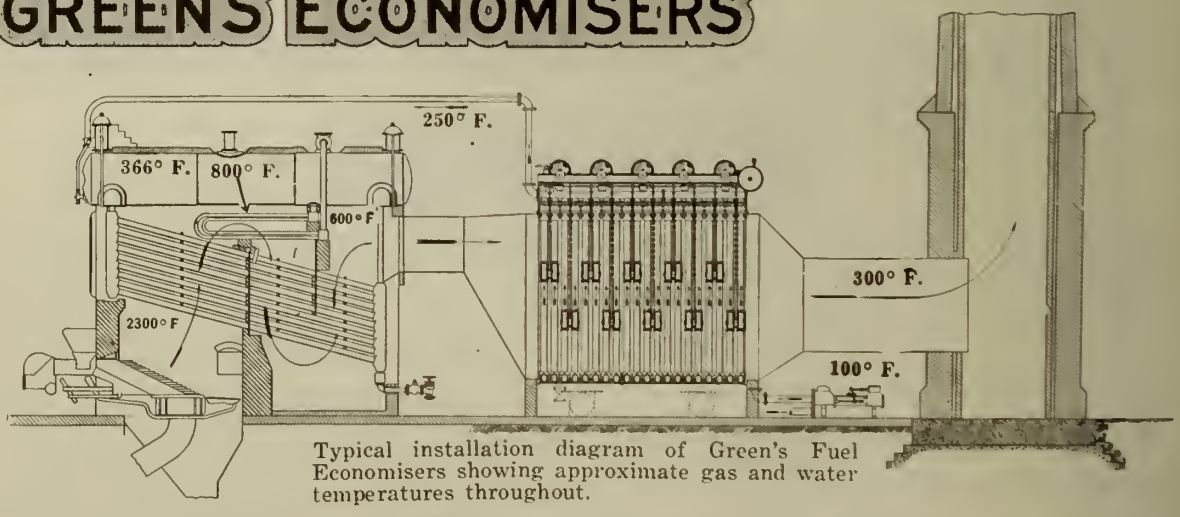
GREEN'S ECONOMISERS



Typical installation diagram of Green's Fuel Economisers showing approximate gas and water temperatures throughout.

At the recent Chemical Exposition in New York, during the fuel economy conference, one of the speakers, a noted engineer, stated that by far the greatest heat loss in the boiler room was in the sensible heat of the exit gases.

The use of extra boiler surface to cool gases below 500° F. does not pay because below 500° F. the heat absorbed per square foot of heating surface does not equal the cost of maintenance. The use of **Green's Economiser** is the most economical method for recovering this loss—it will reduce the gas temperature to a low figure at minimum cost—by transferring the heat of the gases to the feed water, under boiler pressure, thus allowing the boiler to be supplied with water at a temperature slightly lower than the steam itself.

Write for our bulletin No. 151, or call for one of our engineers to inspect and make recommendations for your conditions.

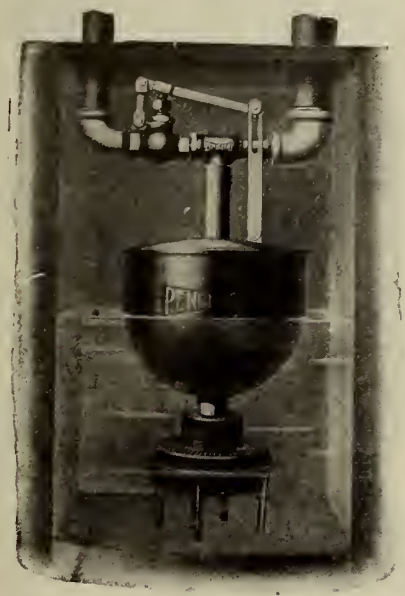
TRADE PENBERTHY MARK.



Illustrating Penberthy Cellar Drainer Installed in Pit or Sump.

AUTOMATIC CELLAR DRAINER

ALL WORKING PARTS ABOVE WATER

LOOK OUT

FOR THE SPRING FLOODS!

Keep Your Basements Dry

There is no excuse for flooded basements or cellars when the Penberthy Cellar Drainer will keep them dry and sanitary.

WHAT IT IS FOR AND HOW IT IS OPERATED

A device for transferring liquids from one level to another with water under pressure or steam as power. The name Cellar Drainer is derived from its commonest use, that of pumping water from cellars, but its utility is not necessarily restricted to this usage. The construction of the Penberthy Automatic Cellar Drainer is admirably simple, being a highly efficient ejector or syphon jet to which is attached a quick-opening, float-controlled valve. Nor is there anything complicated about its operation. The Drainer is placed in the sump or place where the water or seepage collects, a line from the city water supply attached at one side and a line leading to your discharge point (sewer, gutter or wherever it may be to the other side. Then turn on the water and forget it, for as the water rises in the pit the float is raised, and when the right height is reached the valve is opened instantly, allowing the city water to flow through the ejector, cause a suction, and carry the sump water with it to the discharge. As the water goes down the float follows and when the low point is reached the valve closes, to remain closed until enough water collects to again raise the float, when the whole operation is repeated.

in money saved, in coal saved, in time saved to invest in

PLIBRICO
JOINTLESS

FURNACE LINING

A furnace lining full of joints means loss of money through loss of heat and rapid deterioration. There are NO joints in a PLIBRICO lining, therefore no loss of heat —no coal waste—and deterioration cannot start. A PLIBRICO lining is quickly and easily installed, a saving in time. Therefore PLIBRICO is a big-paying investment.

Shipped in steel containers of distinctive appearance as shown at the right. Warehouse stocks in Montreal, Toronto, Winnipeg, Vancouver and Calgary ready for immediate delivery.

Ask for book on Furnace Building.

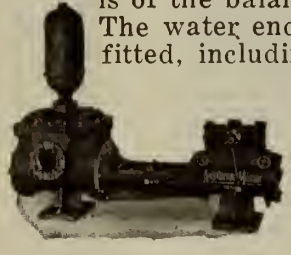
AMERICAN-MARSH PUMPS

SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.

The line also includes—
Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

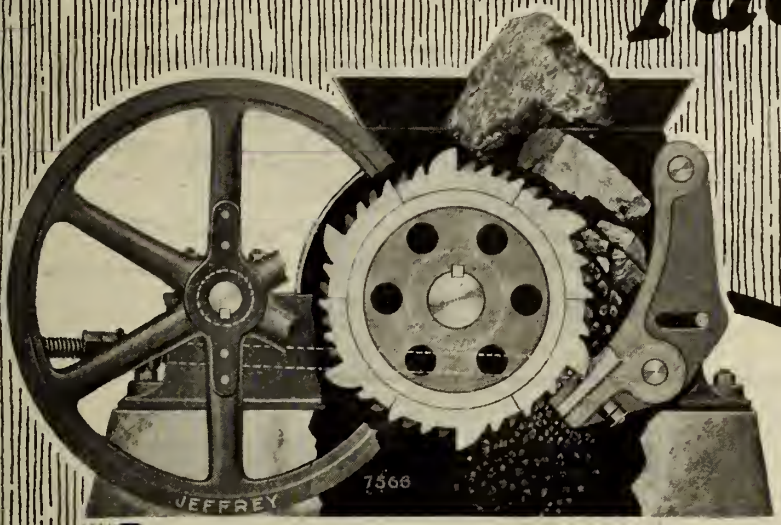
Power plant efficiency = 100%

Factor of Safety = ?



PATENTED

Your plant may be functioning at top-notch speed—there may be close co-operation, scientific management, large output, quick deliveries, and everything operating at the highest efficiency, but at the very minute you may be working under a peak load you suddenly find yourself deprived of a supply of stoker coal and your whole system goes to smash.

You have overlooked the Factor of Safety.

A Jeffrey Single Roll Crusher

installed in your power plant means a real, lasting and dependable Factor of Safety.

It crushes run-of-mine or lump coal to stoker size in one operation and makes your plant independent of Mine, Weather and Traffic Conditions.

Write to-day for copy of Bulletin No. 141-4.

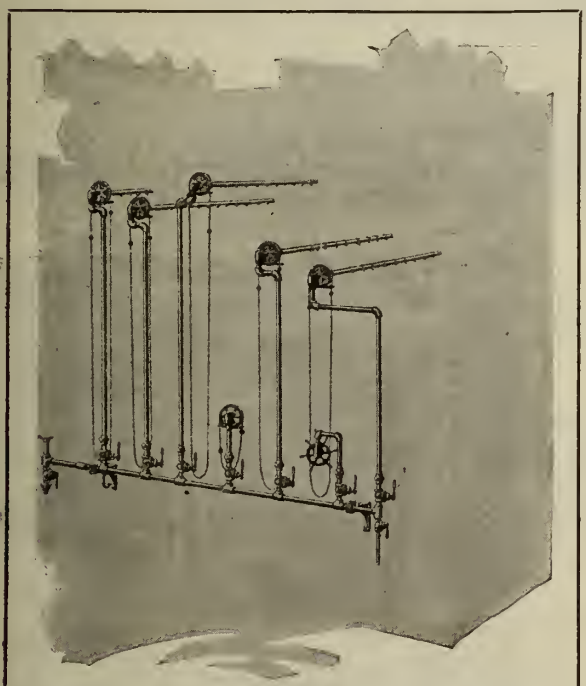
Cleaning Your Horizontal Water Tube Boilers CLEAN!



This illustration shows the Vulcan Soot Cleaner as applied to Horizontal Water Tube Boilers, of the Goldie & McCullloch B. & W., Edge Moor, Keeler, Casey-Hedges, and similar types. Systems of 4, 5 and 6-elements are used for cleaning these boilers, according to size and conditions. As a rule, 6-elements are installed, and sometimes an additional element when a superheater is employed.

SOME manufacturers put off the installation of mechanical soot cleaners because they think this equipment is in the nature of a luxury that can be dispensed with more or less indefinitely.

Were more of these men aware that a very large majority of the **Public Service Corporations** of Canada and the United States—concerns which manufacture power FOR SALE! — have their boilers completely equipped with mechanical soot cleaners, they probably would change their point of view.

Vulcan Soot Cleaners are a tangible, dividend-paying investment. This dividend varies from 20% to as high as 200% or more, depending upon the plant, fuel consumption, fuel cost, etc. No plant can purchase Vulcan Cleaners unless it can be reasonably demonstrated, in advance, that they will PAY.

A little while ago, we prepared a "financial analysis" for a concern that has since installed Vulcans. This analysis has been printed up under the heading "SPENDING $796 TO EARN $1,017.40!' If you are interested in the possible financial advantages that you may derive from Vulcan Soot Cleaners, we shall be glad to send you a copy—of course, quite without obligation. Just write any of our offices listed below.

Let Riley Stokers Reduce Your Costs

Riley Stokers are always on the job—you can rely on them to be at work every day. They are tireless—working all hours of the day and night —without complaint.

Industrial plants can cut their operating costs to a minimum by using Riley Underfeed Stokers. Consider the following facts:—

EFFICIENCY—Boiler tests on Riley Stokers have shown over-all efficiencies of 80% and higher.

LABOR-SAVING—One or two men can replace ten or twelve required for hand firing. Continuous, automatic discharge of ashes means elimination of drudgery in fire cleaning. Labor for ash handling in a well-laid-out plant is negligible.

COMPLETE COMBUSTION—The underfeed method and moving grates intimately mix the proper amount of air and coal, giving perfect combustion.

Catalog H.R4 sent on request.

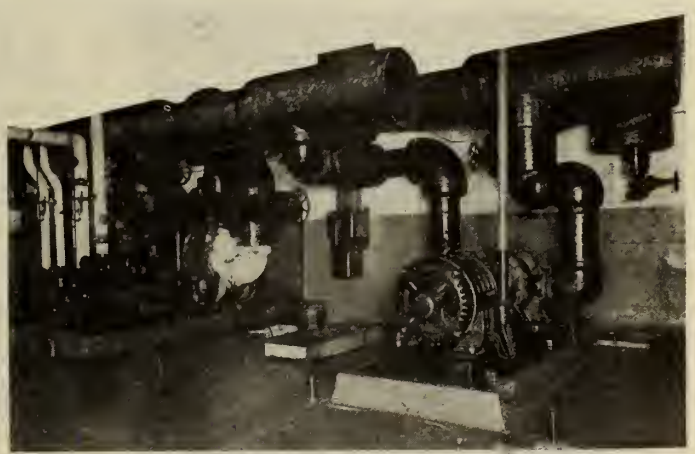
Protected All the Way

CARRYING refrigeration to insulated rooms in uncovered lines is a good deal like wearing a shoe on one foot and leaving the other foot bare. Unbalanced operation results in either case. Certainly it is just as essential to protect your refrigeration on the way to its work as it is to conserve it after it gets there.

Even at the same temperature difference, one square foot of bare pipe surface will lose considerably more refrigeration than a square foot of uninsulated brick wall. With brine at 15° F. and air at 75° F., at least *one ton* of refrigeration is lost *every day*, from 120 feet of 3-inch, or 175 feet of 2-inch bare pipe—a total of 300 tons a year, and you know what refrigeration costs you now.

Whether you have 20 or 200 or 2,000 feet of line you can insulate it with Nonpareil Cork Covering for less than the loss from that line in a single year. Nonpareil Cork Covering eliminates this needless waste, once and for all. Afterward, for the many years the covering will last, that saving is clear profit to you.



Refrigeration losses are reduced to a minimum by the use of Nonpareil Cork Covering on these brine lines in the plant of the Loose-Wiles Biscuit Company, New York City.

You can easily figure pipe line savings for your own plant from the tables included in the 64-page book, "Nonpareil Cork Covering." This is a valuable work on refrigeration loss and cold pipe insulation which every manager and engineer should have. Your copy will be mailed on request, without charge.

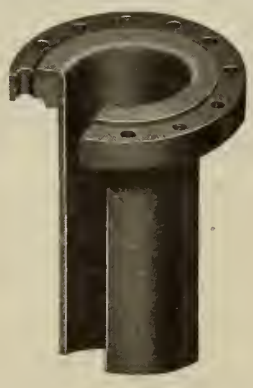
P H FLANGED PIPE JOINTS

SCREWED



P.H. LAP

SCREWED FLANGES.—For general service, our screwed-on flange gives universal satisfaction and is the least expensive. For steam and water lines, at pressures up to 125 lbs. the flange is screwed home and not refaced. For higher pressure, we recommend screwing on the flange until the end of the pipe projects beyond the face, then refacing by taking a cut across the flange and end of pipe, insuring a perfect joint with the gasket bearing on the end of the pipe. This prevents the pressure from working through the thread of the flange, and insures a long life for the joint.

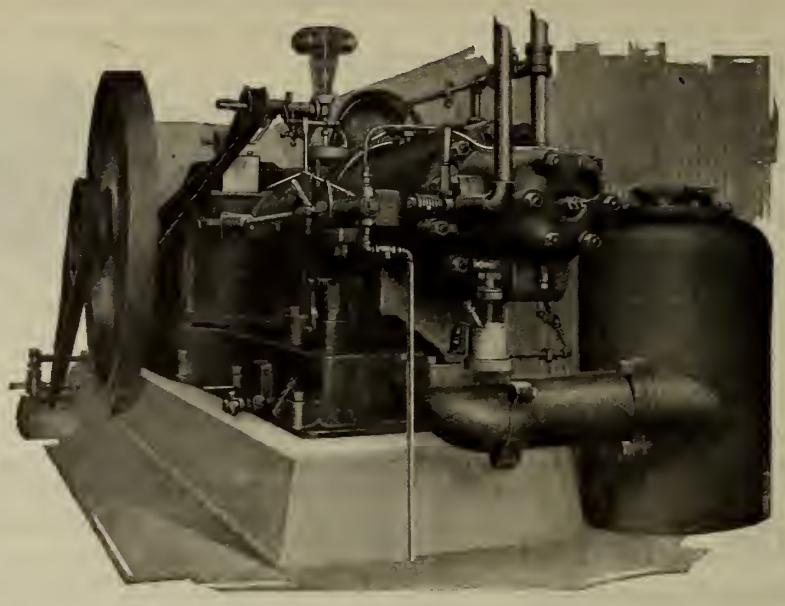
For all High Pressure service, and where it is objectionable to reduce the thickness of the wall of the pipe by threading, we recommend **P H** Lap Joint.

MADE IN CANADA BY

PAGE-HERSEY TUBES, LIMITED

100 Church Street, TORONTO, Ont.

J. T. Mays & Bros., Spring Hope, N.C., operate this 50 h. p. Giant Semi-Diesel Oil Engine. Ask this user why he bought a "Giant," or ask us for the location of a Giant Engine installation near *you*.



Giants not only have the fundamentals of economy, low upkeep and long life, but meet every condition of service, no matter how severe or exacting, with either single or duplex types, in capacities from 12 to 200 h. p. Ask for Bulletin 389.

POWER

Additional Power—Replacement Power—Standby Power

Whether dignifying model-of-efficiency power plants or "roughing it" under adverse outdoor conditions, Giant Semi-Diesel Oil Engines can be *depended upon*. Whether installed as additional, replacement or standby power units, you can *rely* upon Giants. Simplicity, economy and certainty of operation are responsible for their wide endorsement by veteran engineers.

Replacement units must necessarily be the sum-total of what the unit they replace *isn't*. Its defects, inefficiencies and unreliability—whether in the form of broken heads, shaft breakage or hard starting due to loss of compression must be overcome by its successor. Giants not only offset undesirable qualities of less efficient units, but in modern points of design they are unequalled.

Standby power has become as much of a necessity in the power field as *plant insurance* — because it stands between the plant operator and shutdowns by insuring a *constant* source of power supply. But only an oil engine of Giant dependability is eligible for this important guard-duty, a duty so well performed that Giants so installed have subsequently succeeded the "regulars."

COAL AND ASHES CONVEYORS

How long will this Fire Brick last?

Much depends on what's on the trowel

THE life of a fire brick depends largely upon whether the intense heat and flame come in contact with only its face, or with its face, edges and parts of its four sides, which are supposed to be protected by the bond in which the brick was set up.

If the face alone is subjected to the heat, the brick itself conducts that heat away—uniformly.

If the edges and parts of the four sides of the brick are subjected to heat, the brick becomes "heat soaked" and the result is the cracking off or spalling of the surface.

If the sides and edges of the brick are permanently protected, it will last longer—and if all parts, including the face, are protected, it will last still longer.

Therefore, we say that the life of a fire brick depends largely upon what material is used as the bond in which the brick is set.

Unless a bond that will resist expansion and contraction is used, it will crumble and fall out. Unless a bond that will resist high temperatures is used it will melt out.

In either case, edges, corners and parts of the brick other than its face will be exposed.

Johns-Manville Refractory Cements resist expansion and contraction without crumbling or falling out and resist extremely high temperatures without melting and running out. They provide a permanent bond around the sides of the brick, preventing anything but the face from being attacked.

The face itself may be protected by the application of a Johns-Manville Refractory Cement that not only has high heat resisting value, but also prevents the penetration of clinkers into the body of the brick. When clinkers are sliced off brickwork protected in this manner neither the face or any other part of the brick is torn away with the clinkers.

Some Results With Mechanical Soot Blowers

This Article Considers Some of the Most Recent Tests With Coal, Pulverised Fuel, and Oil—Marked Increases in Boiler Efficiency With Each of These Fuels.

By ROBERT JUNE

SOOT, it has been stated, is the best heat insulator known, being more than five times as effective as asbestos in preventing heat transference. Those of us who have to deal with the soot problem continuously know that this statement is literally true. You can no more expect efficiency out of a boiler, the fire surfaces of which are coated with soot, than you can expect efficiency from a man with a bad cold. There is congestion and bad circulation in both cases.

If you want to keep up steam when the soot piles up you will have to pile in more fuel. This fact has been strikingly illustrated in some recent tests. Mechanical soot blowers were installed on boilers fired with coal, pulverized fuel and fuel oil. These tests show clearly that clean tubes—clean as only mechanical soot blowers can make them—are absolutely essential to the maintenance of high boiler efficiency.

In this article then, instead of discussing the advantages and disadvantages of mechanical soot blowers — questions which center in the design and construction of the equipment—we will deal with some of the actual results secured in typical power plants, and will reserve our consideration of mechanical features and the types of equipment for different boilers until next month.

Test At Large Railroad Shop Boiler Plant

During the winter of 1918-19, one of the big American railways decided that the cost of producing power at one of its large shops was excessive, and that the posssibility of effecting a reduction through the medium of mechanical soot blowers should be thoroughly investigated.

Bigelow-Hornsby boiler No. 544 in the west boiler-room, which was selected for test, is rated at 625 horse-power. The stoker under this boiler is a Taylor 7-retort underfeed type, having a grate area of 105 square feet, with inclined grate. Forced draft was supplied to this stoker by 1 to 3-inch Sturtevant turbine-driven, multivane, double-inlet fans.

In this test, the forced draft and the stoker drive were separated and the stoker was driven by one of the Westinghouse engines recently installed on the boiler room floor for the driving of stokers. Induced draft was obtained by means of fans located at the uptake to the stack.

On boiler No. 544 steam flow was obtained by means of two meters, one an integrating-recording-indicating General Electric meter, already installed and used in tests, and the other a newly-installed Bailey boiler meter. Weight of coal was obtained from the travelling weight hoppers and lorry tickets. A revolution counter was placed on the Taylor stoker to count the revolutions of the main power shaft. The thermometers for obtaining superheated steam temperature and that for obtaining feed water temperature were placed in thermometer wells in their respective pipes at the top of the boiler, as in previous tests.

Uptake temperature was obtained from three pyrometers inserted into the flue above the damper, and inserted at 4, 5, and 6 feet respectively. The cold junction temperature was obtained by means of an indicating thermometer suspended over the cold junction of the pyrometers. Steam pressure was obtained from the steam gauge in regular service on the drum. A steam correcting thermometer for obtaining the superheated steam temperature corrected was used. The carbon dioxide of flue gas was obtained by means of a sampling tube already installed and used in previous

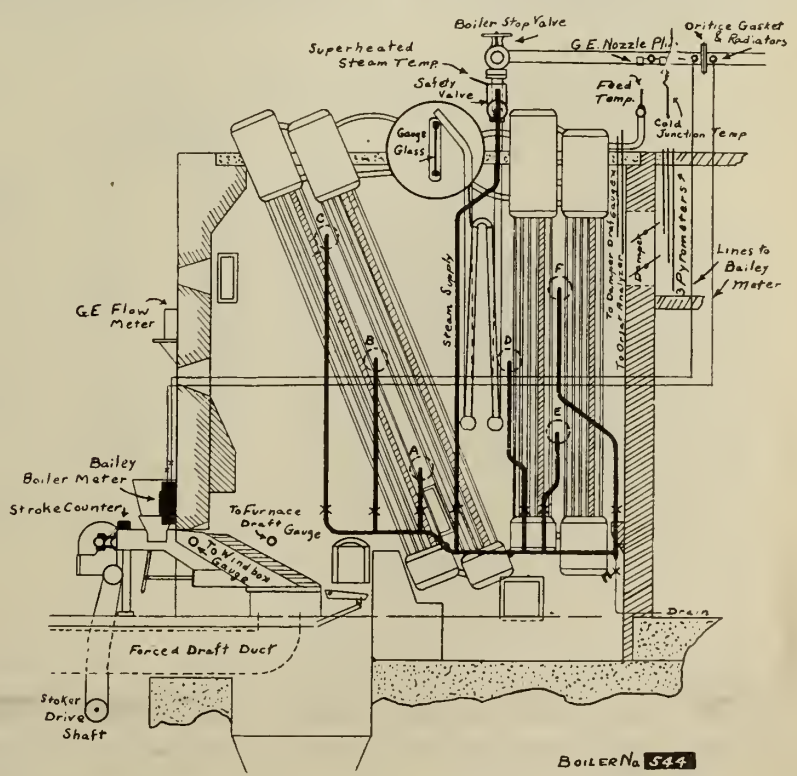

FIG. 1—BIGELOW-HORNSBY BOILER SHOWING LOCATION OF RECORDING DEVICES

tests in conjunction with a standard Orsat gas analyzer. Draft over the furnace and at the damper was obtained on the indicated gauge. Presssure in the wind box was indicated on the lower gauge and in the recording pressure gauge. In addition to the above, the Bailey meter indicated the draft over the furnace and the air flow through the boiler, the latter being obtained by means of 1½-inch pipe connections, one to the combustion chamber over the furnace and the other in front of the damper at the same height as the first. The various items indicated above, and constituting the testing apparatus of this boiler, are shown in the accompanying sketch.

Boiler No. 544 was cut in on the line at 5 a.m., February 3, 1919. The duration of each run was 24 hours. At the beginning of each run the fire was cleaned and the hopper filled. The tail gate was cleaned whenever found necessary by observation of the fire. This varied from about every two to four hours, depending on the load. On this boiler, eight tests in all were made, the first four being with soot blowers, and the second four being without soot blowers, attempting to reproduce the conditions of the first four as nearly as possible.

In doing this the fire-room crew and the tester were guided by the average conditions attained in the first four runs. Readings were taken every 20 minutes. The steam utilized by the soot blowers was not registered by the steam flow meters. Readings were taken as follows: steam flow, air flow, furnace draft gauge, windowbox pressure, the speed of the stoker line shaft, the number of revolutions of the stoker power shaft, steam pressure and carbon dioxide in the flue gas. Forced draft was obtained from No. 3 blower which was isolated from the other blowers by closing the division damper. It was kept running throughout the entire test, and the draft to the boiler was regulated by means of the control at the boiler.

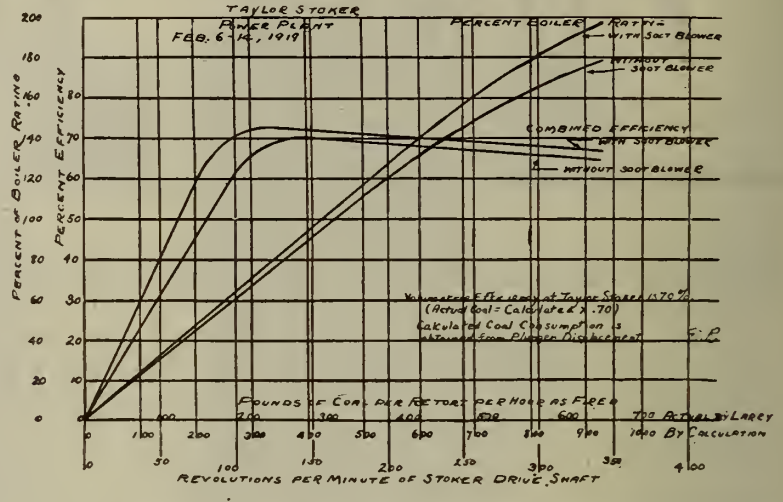

FIG. 2—RESULT OF TESTS ON SOOT BLOWERS ON BIGELOW-HORNSBY

A summary of the principal data and results of the test on boiler No. 530 is given herewith at Table I. The same material has been tabulated for boiler No. 544, but as it does not differ materially, it is not here included.

Average value of the flue gas temperature for the series with soot blowers is 481.0 deg. F., against 569.0 deg. F. without soot blowers. This represents a decrease of 88 deg. using soot blowers, and means that with the soot blowers in operation, the boiler has absorbed more heat from the bases, due to cleaner heating surfaces, than without soot blowers.

It has been stated previously that with the present practice of cleaning the boilers with the hand lance, each boiler is cleaned every four to five days. In the tests on boilers Nos. 530 and 544, without soot blowers, in order to reduce this condition, the series was started with the boiler heating surface clean and then left without cleaning during the series.

If the series had been extended for, say, an equal period or longer, and if during that time the regular hand method had been used to clean the boilers on the regular schedule, it is very probable that a still greater rise in flue gas temperature and still greater decrease in combined efficiency would have resulted. It is safe to say that a more exact test along the line indicated would show better results.

In addition to the above, may be mentioned the fact that operation of soot blowers does not require the banking or shutting down of the boiler, while in order to remove the soot by the hand

*72 hours.

method it is necessary to shut down the boiler for two or three hours, during which time the boiler setting cools and must be warmed up again. Here is a loss which is eliminated by the use of soot blowers.

In conclusion, it should be noted that these tests were conducted in a manner

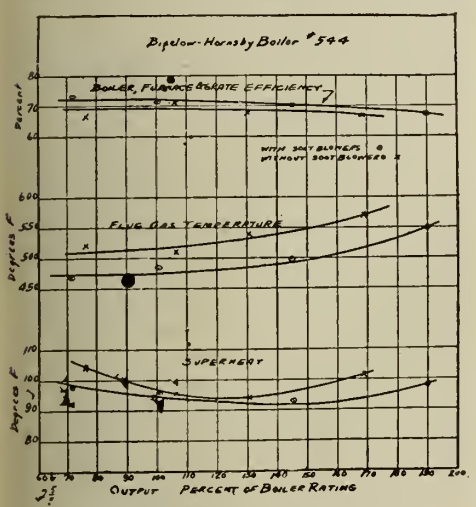

FIG. 3—GRAPHIC SUMMARY OF RESULTS ATTAINED BY USE

calculated to indicate a minimum rather than a maximum improvement by the use of soot blowers. The tests would undoubtedly have been fairer if the use of soot blowers before making the tests had been refrained from, employing the hand lance only to clean the boilers at the regular periods of cleaning. Had this been done, the boilers would not have had the advantage of being cleaned thoroughly by mechanical soot blowers when they entered the hand-hose test.

Mechanical soot blowers are just as important, just as necessary with pulverized fuel as with other types. As a matter of fact, in practically all successful installations, where pulverized fuel is used, the boilers are equipped with mechanical soot blowers. The tubes should be cleaned by the blowers every six hours or oftener. As the temperatures are high, the blowers should be

TABLE II.
Comparison of Composite Results With and Without Diamond Soot Blowers.

In East Boiler Room	5,503.19	
Total saving	$14,063.05	

constructed of some such material as calorized metal in order to withstand the hard surface conditions. The regular use of mechanical soot blowers will save from 4 to 8 per cent. of fuel, as well as a large amount of the labor required for cleaning.

Soot Deposits in Oil Fired Boilers

The soot deposit resulting from the combustion of oil is in the nature of a pure carbon mixed with a slight amount of oil. It is somewhat fluffy in appearance and adheres readily to the tubes, but is easily cleaned and removed from them under the operation of a steam jet. It is entirely different in character from the soot resulting from combustion of coal on account of the absence of ash, etc., and the presence of greater or less quantities of unburned oil, which, going through the boiler, tend to deposit on the tubes in combination with the soot. If this formation is not removed at regular intervals it soon crystallizes or carbonizes on the tube and must then be scraped off with rods or bars.

Soot deposits from oil-fired furnaces have much greater insulating effect than those occurring with coal-fired furnaces. There are two reasons for this: first of all, the deposit is in the nature of a pure carbon which has greater insulating properties than various ash constituents found in soot from coal; second, the deposit being of a somewhat fluffy adhesive nature, is usually found to envelope the entire tube as compared with coal deposit, which usually consists of soot, dust and ashes, building on top of the tube and leaving the underside more or less clean.

For some time after oil came into use for boiler furnaces, the impression prevailed that oil-fired did not require as frequent or as thorough cleaning as coal-fired. The efficiencies of oil-fired boilers were generally higher than those obtained where coal was used as fuel, due to more perfect combustion with a smaller quantity of excess air, and this improvement was for some time accepted on its face value as the best obtainable. With the increasing use of oil as fuel in the past few years, it was inevitable that detailed tests should be inaugurated of the performance of oil-fired boilers with and without mechanical soot blowers.

These tests developed the fact that mechanical soot blowers are absolutely essential to the development of the highest efficiencies on oil-fired boilers. As an example, attention is called to the results of the following test by the Pacific Gas and Electric Company.

TEST DATA BEFORE USING SOOT BLOWERS.

Time A.M.	Stack	Temperature Sup. Steam	Load Meter
10.15	550	500	4.2
10.30	550	502	4.0
10.45	555	498	4.0
11.00	557	498	4.1

TEST DATA AFTER USING SOOT BLOWERS

Time P.M.	Stack	Temperature Sup. Steam	Load Meter
2.30	485	495	...
2.45	485	506	...
3.00	482	504	...
3.15	483	505	...

Test Results	Before	After
Load Meter	4.075	4.175
Per cent. rating, per cent.	101.85	105.38
Steam pressure gage, lbs.	199.5	200.75
Superheater steam temp., deg.	499.5	502.5
Stack temperature, deg.	553	483.75

These results show that the soot blowing caused the temperature of the stack gases to fall from 554 deg. to 483.75 deg., making a difference of 69.25 deg. or 13.05 per cent.

Also the temperature of the superheated steam was raised from 499.5 deg. to 502.5 deg., a rise of 3 deg. or 0.6 per cent.

The direct effect of the use of soot blowers is a saving in fuel of 3.9 per cent.

Texas Company, Port Arthur, Texas, found a saving of 5.5 per cent. fuel by the use of mechanical soot blowers and as a result ordered an equipment for 30 oil-fired boilers. As this company is in the oil producing business its action is particularly illuminating.

These tests were followed by others at some of the large western central stations. On one of them, the boiler, a large Stirling, was taken off the line, and the tubes, superheater, etc., washed clean. The boiler was then fired and an evaporation rate of 37,000 pounds of water an hour and 14 per cent. CO_2 was maintained. At the end of 24 hours the soot blowers were operated and were used for 24-hour periods for the remainder of the test with the equipment. During

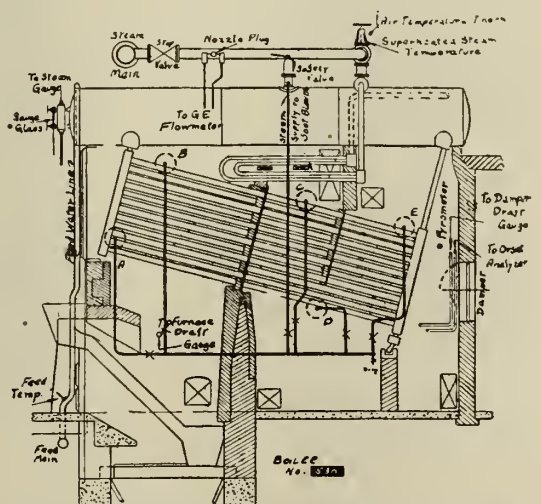

FIG. 4—ARRANGEMENT OF SOOT BLOWER UNITS AND RECORDING APPARATUS ON BABCOCK & WILCOX BOILER.

these tests, readings were taken at 15-minute intervals of the water-rate, CO_2, draft, oil and superheat. When using the blowers, the temperature dropped to 525 deg. and rose to 540 deg. in about 15

NUMBER OF HOURS SINCE DUSTING

FIG. 5—RISE IN TEMPERATURE OF FLUE GAS DUE TO SOOT.

minutes. It ranged around 540 deg. for about 16 hours and then crept gradually up to 590 deg. at the blowing period when it again dropped to 525 deg. This was the regular daily performance throughout the test while using the blowers.

At the end of a seven-day period the boiler was given a final blowing and thereafter operated under the usual plant conditions; that is, without any cleaning at all. At the end of the first 24-hours' run, the temperature had risen to 590 deg.: at the end of the week it had risen to 680 deg., and at the end of 10 days had risen to 720 deg., at which point it seemed to hold. But they were not able to maintain the evaporation rate, which dropped to 34,000 pounds per hour. The saving effected by soot blowers amounted to 6 per cent.

Despite the war emergency, with its constant urge to speed rather than thoroughness, the Emergency Fleet Corporation made some detailed tests of Diamond soot blowers before adopting them. These tests were conducted at Burlington, Iowa, under the direction of the Bureau of Mines.

The boiler selected was the Foster Marine water tube, and was one of a large number then being built by the Murray Iron Works of Burlington, Iowa, for the Power Specialty Company of New York, for delivery to the Corporation. The tests extended over a period of a number of weeks and covered a wide variety of operating conditions, with boilers forced to high rating at times, with different conditions and drafts.

In addition to proving the necessity of soot blowers to economical operation, the tests threw some important light on soot blower construction. For instance, in boilers burning fuel oil, draft conditions are very low, running from .02 inch in the furnace up to .08 inch in the uptake. If soot blowers were designed so that all nozzles emitted steam at the same time, a curtain or blanket of steam would be ejected into the boiler at high velocity, with the result that it would either put out the fire or materially interfere with the draft. The bad effects of interfering with the draft can hardly be overstated. As a result of such conditions, all of the factors in the operation of the boiler become unbalanced. This applies to the feed of oil to the furnace, the maintenance of even steam pressure and the injection of the feed water. In place of a normal even operation, a condition of ebb and flow takes place which may last for an hour or more before conditions again become normal. Necessarily, this entails additional work on the part of the fireman who finds the whole routine and operation of the boiler room upset.

In order to take account of this condition, the soot blower for hollow-staybolt boilers is made up in vertical sections, each under the control of its individual valve. This arrangement permits of blowing three or four vertical rows of tubes at one time, thus avoiding all interference with the draft.

On stationary boilers of the horizontal water-tube type, vertically baffled, and on vertical boilers, where revolving soot blower units of the Diamond Model G type are commonly used, the use of fuel oil calls for little change in construction. Care is taken in locating the units to be sure that they blow with the draft. In addition it is sometimes found advisable to stagger, or offset, the blower nozzles so that they do not all blow in the same direction at the same time.

As a result of the Burlington tests hundreds of oil burning vesels, built by the Emergency Fleet Corporation, were equipped with mechanical soot blowers. In conclusion, the mechanical soot blower for oil-fired boilers is here to stay, and the use of blowers on such boilers is fast becoming as common as the use of blowers on coal-fired boilers.

The exact effect of moisture in connection with spontaneous combustion is not known and the evidence of laboratory experiments is contradictory. The repeated wetting and drying of coal seems to increase the tendency to spontaneous combustion. This may be due to the breaking up of the coal which such alternate wetting and drying occasions, even if there is no chemical reaction between the water and the coal. It is not wise to put coal into a pile or to store coal on a damp base if it can be avoided. After a rain or snowstorm, a coal pile should be carefully inspected and watched.

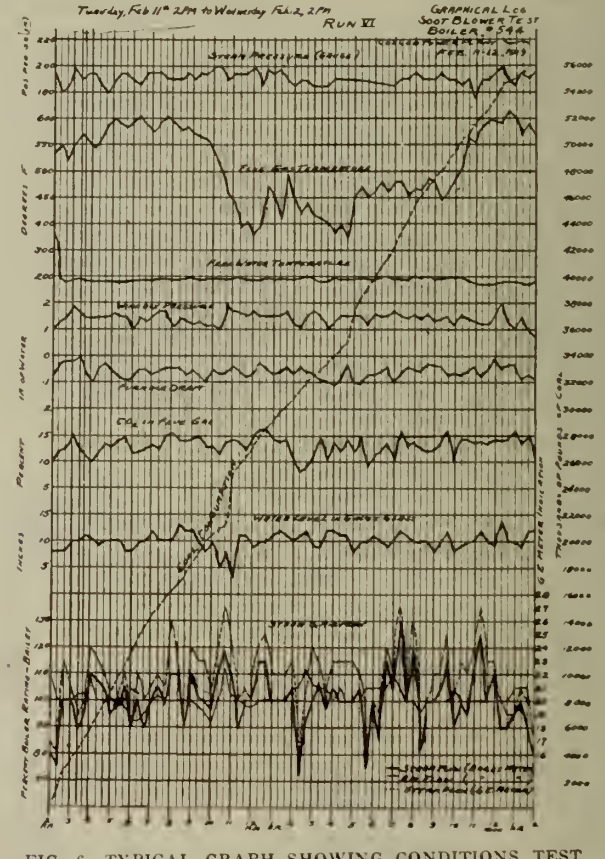

FIG. 6—TYPICAL GRAPH SHOWING CONDITIONS TEST OF SOOT BLOWER.

CATALOGUES.

The Jeffrey Manufacturing Company, Columbus, Ohio, have issued a new booklet describing their standardized scraper conveyors. The booklet is known as Catalogue 257. It is profusely illustrated, and scraper conveyors for practically every conceivable purpose are described. Specifications for ordering, and diagrams showing general overall dimensions, are given.

Toronto No. 1 C.A.S.E. Stage A Real Success

THE Toronto No. 1 C. A. S. E. held their annual banquet at Yonge's banquet hall on March 23. The function was the complete success which we have learned to expect of any effort of this lodge.

About one hundred members, ladies, and guests were on hand when the proceedings were opened by the evergreen "Dad" Wickens. From the time grace was sung till the close of the proceedings at nearly midnight everything went with a swing. No details were neglected, and one gentleman, connected with a famous firm of bricklayers, provided pencils for the guests to take notes with. Much satisfaction was felt in that he had not distributed bricks.

After the excellent dinner had been properly attended to the toast of the King was honored in the only medium now available. Some of the supply men present were heard to complain that ginger ale alone always upset them, but as several of these gentlemen have lived for years in Montreal, nobody took any notice of them.

The first item on the programme was presented by Mr. Howard Fletcher, who played "The Palms" on a one-string violin of home manufacture. He got quite a lot of music out of this unlikely looking instrument, and followed up with "O Promise Me" for an encore.

Mr. C. Mosley, of the examining board, in a short speech introduced to the assembly Mr. W. A. Crockett, one of the original members of the C. A. S. E. and ex-M.P.P. for Labor party. Mr. Crockett, in an exhaustive discourse, reviewed the C. A. S. E. from its inception to the present day, and through its future. He also included a general survey of Toronto, Hamilton, the Province, and the Dominion. The conclusion of his speech was the signal for loud applause.

The Ontario Examining Board was proposed by Mr. Sweet, of Hamilton, and responded to by Mr. James M. Brown, chairman of the board. Mr. Brown, in the course of his remarks, took the opportunity to pay his colleague, Mr. Moseley, a well deserved tribute, which was heartily approved by the audience. Mr. Brown gave a clear account of the board's work, and the aim they had for the future. He said the board intended to make the Ontario first-class certificate the equal of any certificate issued by any other body in the world.

Mr. Bly, of Toronto No. 1, proposed the health of the Grand Lodge, which was responded to by Mr. Ellis, Grand Lodge secretary and member of Hamilton No. 2. Mr. Ellis, in a short and forceful speech, showed what the C. A. S. E. were doing to help out their members in an educational way, and expressed the hope that more advantage would be taken in the future of these opportunities afforded. The Grand Lodge now have a lantern and a large number of instructive slides available for any lodge that applies, and the executive would like to see it used much more than it is. Mr. Ellis spoke of the legislation now on the statute books, and wished it would be more strictly enforced.

The "Supply Men" was proposed by Dad Wickens, and replied to by Mr. Gordon Keith, of "Canadian Manufacturer." During the evening songs were contributed by Mr. Jack Davies, and by Mr. T. H. Fenner, of "Power House."

Some of the guests present were Mr. Gordon Keith, "Canadian Manufacturer"; Stanley Mock, Jenkins Bros.; W. R. Sexton, of W. R. Sexton Co.; Mr. Worthington, of Darling Bros.; Mr. W. H. Auger, of Geo. W. Cole, Ltd.; C. B. Turner; T. H. Fenner, "Power House."

Much credit is due to the organizers of this very pleasant function, and we are sure no one will object to a large share of it going to the energetic old "Dad," whose years continue to sit so lightly on him. The Toronto Lodge can be heartily congratulated on the success of the banquet.

OTTAWA LODGE NO. 6, C.A.S.E.

Ottawa Lodge No. 6 held an open meeting on the evening of March 24th, which was well attended and very successful. The lodge was opened by the officers and members, and after this ceremony the doors were thrown open to the public. A goodly number of engineer non-members availed themselves of the opportunity to hear the lecture on Green's economisers, delivered by Bro. George Lee, boiler inspector for the Provincial Government.

The lecture was illustrated by the lantern belonging to the lodge, the slides being kindly lent for the occasion by the Green Economiser Co. These lantern lectures, of which there have been several during the past winter, have proved very successful, and have resulted in a large number of new members joining the lodge, as well as a number of old members taking up their membership which had been allowed to drop. The executive hope soon to have another open meeting with an illustrated lecture. Arrangements for the annual convention of the association, which will be held in Ottawa on June 28th, 29th and 30th, are well under way, and the officers of the lodge say they will make it a convention to be remembered. They have something up their sleeve in the way of a souvenir, which is confidently expected to put in the shade any previous efforts along this line.

Ottawa Lodge is certainly setting an example to the other lodges worthy of following.

MONTREAL LODGE C.A.S.E.

At the recent meeting of the No. 1 Lodge Montreal C.A.S.E., held on March 24th, an interesting lecture was given by Mr. Evans on the Rees Ro-Turbo Pump. The meeting was as usual well attended, and great interest in the proceedings was evidenced by all present. It is pleasing to note that Montreal Lodge is keeping up its reputation for educational meetings. Some of the other lodges are evidently going to equal, if not exceed, that reputation, as the news from Ottawa and Toronto Lodges would indicate.

MAKING BOILERS SAFE

To operate boilers, and especially water-tube boilers, with safety it is necessary to prevent the water becoming too dense on account of the salts dissolved in it. A continuous means of measuring the density of the water is therefore most important, and it is supplied by a simple "densimeter" invented and manufactured by a British firm. In this appliance a column of distilled water is balanced against a column of water from the boiler, and the difference in the levels of the two columns is a measure of the density of the boiler water. A scale is provided by which the precise difference in levels can be easily read, thus giving the engineer in charge a ready warning when the danger point is being reached. This apparatus has received the approval of the boiler insurance companies.

LARGEST AEROPLANE ENGINE ON RECORD

Great Britain claims the credit of having built the largest aeroplane engine on record. Recently there was tested in a factory near London, England, an engine which developed over one thousand horse power. This engine, which was built to the order of the Royal Air Force, has sixteen cylinders, weighs close on one ton, and is most economical in fuel and oil consumption. Its influence on the range, speed, and carrying capacity of aeroplanes is expected to be considerable, and its performances in the air are awaited with the keenest interest by aviation experts.

The Effect of Load Factor on Station Costs

What Load Factor Is—How the Investment is Affected by Load Factor—Influence of Load Factor on Location of Site—The Selection of Equipment

By PETER JUNKERSFELD

THE annual load factor is an indication of the number of hours per year that the dollar of capital expenditure in a steam station can be kept at work. The expense of using this dollar is just as great when it is working 100 hours as when working the full 8,760 hours of the year. The returns are, however, in direct proportion to the number of hours per year that this dollar is kept at work, or in other words, to the annual load factor. For example, if the annual load factor of a power station is increased from 30 per cent. to 60 per cent. the fixed charges per kilowatt-hour are cut in half.

Load factor is the ratio of the average to the maximum output during any definite period of time. It is usually based upon an average demand for, say, 15 min., and upon output for a day, week, month, or year. It may apply to a system having many generating stations and serving many communities, or merely to one power station or even one unit in a power station.

The annual load factor of a central-station system nearly always changes very slowly. Special effort to secure a well-diversified business together with the new uses of electricity which are constantly arising contributes substantially to improvement in load factor.

The ordinary factory, working a 44-hour week with the usual lay-offs for holidays, keeps a power station busy for only one-quarter of the 8,760 hours per year. Residence and street lighting tend to improve load factor in the summer, but are less and less of a help as the days grow shorter, until they finally change from a blessing to a burden upon the plant, during the months when the lighting peak overlaps the end of the factory or business day..

Investment as Affected by Load Factor

The cost of energy is made up of two principal elements, the fixed charges and the operating and maintenance expenses. In the case of the fixed charges we must use annual load factor because fixed charges run on year after year. Suppose that one power station has cost $100 per kilowatt. At 15 per cent. per annum the fixed charge per kilowatt would be $15 each year. With an annual load factor of 30 per cent., the fixed charge per kilowatt-hour would be 0.57 cent. If the load factor is increased to 70 per cent., we find this fixed charge per kilowatt-hour cut to 0.24 cent.

This comparison, of course, is not wholly a fair one, because a station properly designed to operate at a 70 per cent. load factor would cost more to build, although less per kilowatt-hour to operate, than one of equal capacity but properly designed for a 30 per cent. load factor. Its boilers would have been rated differently, turbines of different individual capacities and perhaps different efficiencies might have been selected, the condensers would have been designed more liberally and higher-efficiency equipment would have been selected wherever economical with the higher load factor. Even supposing that those features boosted the first cost $20 per kilowatt, we would still save probably one-tenth of a cent per kilowatt-hour in the combined fixed charges and operating expenses in comparison with an attempt to impose a 70 per cent. load factor on a plant properly designed for one of 30 per cent.

FIG. 1 — RELATIVE GENERATING COSTS, SHOWING THE EFFECT OF DESIGNING A STATION FOR TOO HIGH A LOAD FACTOR.

The curves in Fig. 1 show the relative costs of energy from a power station designed for a 70 per cent. annual load factor when operated at various other load factors. Note at 40 per cent. annual load factor the lower cost of energy obtained from a station designed for a 40 per cent. annual load factor. The lower fixed charges on the 40 per cent. station more than offset its higher operating expenses.

Financial loss will result whenever it becomes necesary to operate a power station at a substantially higher or at a substantially lower annual load factor than the annual load factor for which the station was properly designed. Suppose that the station mentioned previously were one of several stations supplying a light and power system. Assume that at the time of its construction it were intended to operate it on a base load at a 70 per cent. annual load factor, whereas the other stations supplying the system were to be operated only to carry peak loads on account of their inferior efficiency. Assume also that within a few years on account of rapid growth of load another larger station, not previously contemplated, were built having greater efficiency and that the station first mentioned no longer were operated on the base load but were operating at a 30 per cent. annual load factor. We at once see that we are then using an unnecessarily expensive tool where one costing $20 less per kilowatt would do the work just as well and at less total cost per kilowatt-hour.

Similar financial losses may occur in a single power station supplying a rapidly growing load. When a new unit is installed in a power station it is important to know approximately how soon another will be required. Each succeeding unit is frequently larger than the preceding ones, up to the practical limit of size available for the particular purpose. The increased size is usually accompanied by increased efficiency. The units of highest efficiency carry the bulk of the load. The extra price paid for extra efficiency in a power-station unit sometimes results uneconomically due to another larger unit being installed earlier than anticipated.

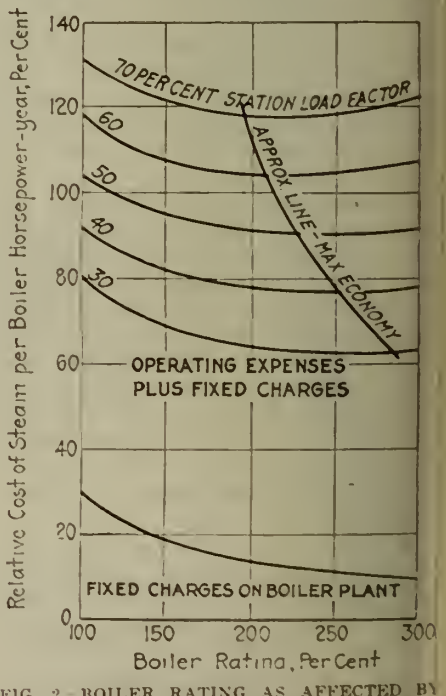

FIG. 2 — BOILER RATING AS AFFECTED BY ANNUAL LOAD FACTOR ON THE STATION

The cost of an error of judgment or the extra expense due to an unexpected change in the annual load factor at which a station or unit is operated may therefore be considerable.

Central-Station Location

The location of a central station relative to its raw-material supply and to the point of delivery of its finished product should be influenced greatly by load factor. In the selection of a site, condensing water is usually given first consideration. Transporting it adds greatly to the station fixed charges, while cooling it artificially causes inefficient operation. A very low annual load factor, likely to prevail over a long period of years, sometimes justifies artificial cooling of condensing water if the station may thereby be located near the load with a minimum investment in transmission lines or cable. With a large annual load factor the additional operating expense due to cooling the condensing water might be so large as to entirely outweigh the fixed charge on the transmission line so that the plant would be located where condensing water is available. In weighing the relative costs, the operating expense at either location must be added to the fixed charge before the more advantageous site can be determined.

Selection of Equipment

Load factor determines the quantity of fuel consumed by a power station and has considerable influence upon the efficiency with which it is burned. Starting, stopping and standing by as well as operating equipment only partly loaded, as is required at low daily load factors, inevitably result in a high coal rate.

One of the first problems, if the station be a new one, is to determine the boiler pressure. High efficiencies can be obtained with high boiler pressure. Construction cost, on the other hand, increases rapidly with increases in pressure. The economical pressure should usually be determined by the extent of the use of the equipment, that is, by the annual load factor.

An arbitrary assumption of steam pressure or an arbitrary selection of certain principal items of equipment may so definitely restrict the design that the full financial benefits of a consideration of load factor in the later selection of additional equipment may not be realized. The most far-reaching power-station engineering is done during the conception of the project, and it is at this time, when fundamental decisions are being made which will either help or hinder the engineering construction and operation of the station, that load factor should be given the greatest consideration. This means not only the immediate load factors but also the load factors that could reasonably be expected during the probable life of the equipment.

Reference has been previously made to the differences in boiler rating for which central-station boiler plants would be designed for operation at different annual load factors. This depends upon the cost of the boilers and combustion equipment, their efficiencies at various loads, the cost of labor and maintenance at various loads, and the fuel required for banking and starting. Fig. 2 shows for a particular case, selected as an example, the effect of load factor on the most economical rating at which boilers should be operated to carry the station peak load. Note the manner in which this economical rating increases as the load factor diminishes.

The rating is only one of a number of boiler-plant problems that arise which must be solved on the basis of load factor. The type and design of the boiler, the length of its tubes, the number of rows of tubes wide and the number of rows high, the combustion equipment, the location of the bridge wall and the baffles, and the size and shape of the furnace, should all be determined by reference to the total load factor on the station as well as the anticipated load factor on the individual boilers. The use of economizers even in large stations cannot be justified at very low load factors.

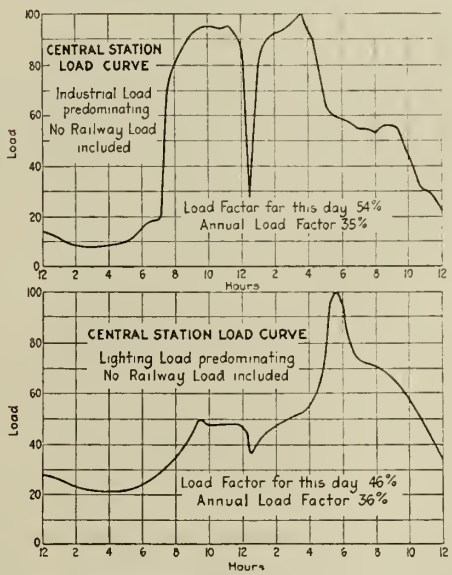

FIG. 3—TYPICAL WEEK DAY LOADS AND CURVES.

The economic selection of turbo-generator units may be made upon the basis of size, speed and other factors. The speed influences both the cost and the efficiency of the unit, and is very important in relation to the average annual load factor at which the machine will operate over a period of years.

The selection of a surface condenser should be made largely from the point of view of the annual load factor. A high load factor anticipated for a unit for a long period of time would justify a condenser of large surface so as to obtain a high efficiency in operation.

The foregoing does not attempt to mention the many power-station appurtenances contributing to higher efficiency which should be omitted from the station designed to operate at low annual load factor, but which might be justified if the station annual load factor were higher. On the other hand, it should not be overlooked that there are some instances in which it is more economical to buy more expensive equipment for low load-factor conditions than for higher load-factor conditions.

The engineers who design a power station fix the upper limit of its operating efficiency by the selection and arrangement of equipment. If this is properly done for the particular load and load factor, the total cost of power from that station, including the fixed charges upon the investment, will be a minimum if the station is properly operated and maintaned. If the selection and arrangement are not made wisely the station thereafter will be handicapped either by excessive fixed charges or excessive operating expenses.

Operating Expenses

The expense of superintendence and station administration is more or less fixed for a given size of station, so that a change of load factor would not influence it in total amount. Boiler labor may be considered as composed of two parts, one of which depends upon the capacity of the station alone, and the other of which, for a station of given capacity, would vary with the daily load factor upon the station. Mechanical labor would be influenced by daily load factor to a less degree, but would depend upon the number and size of the main generator units. The electrical labor would be influenced more by the number of feeders or the number of kinds of current distributed than anything else.

Fuel is usually an item of greater expense than all others and, as pointed out previously, it is dependent upon load factor. Efficiency in the use of fuel is greater at the higher load factors. As an example of the effect of load factor upon station operating expenses, a hypothetical case may be taken of a station containing units of various sizes which might have operating expenses as shown in Table 1. Note the fuel expense as compared wth the total.

Load factor alone does not by any means determine the amount of fuel which a central station of a given size should consume. The shape of the daily load curve is of almost equal importance in its effect upon the efficiency with which the fuel is burned. The shape of the load curve is in turn dependent upon the character of the business served by the central station. This is illustrated by the two examples of central-station load curve given in Fig. 3. In both instances the lighting peak overlaps the day load, but on acocunt of the predominance of factory load in the business of one of these stations an exceptianally favorable shape of load curve is obtained as well as a relatively high load factor for the day.

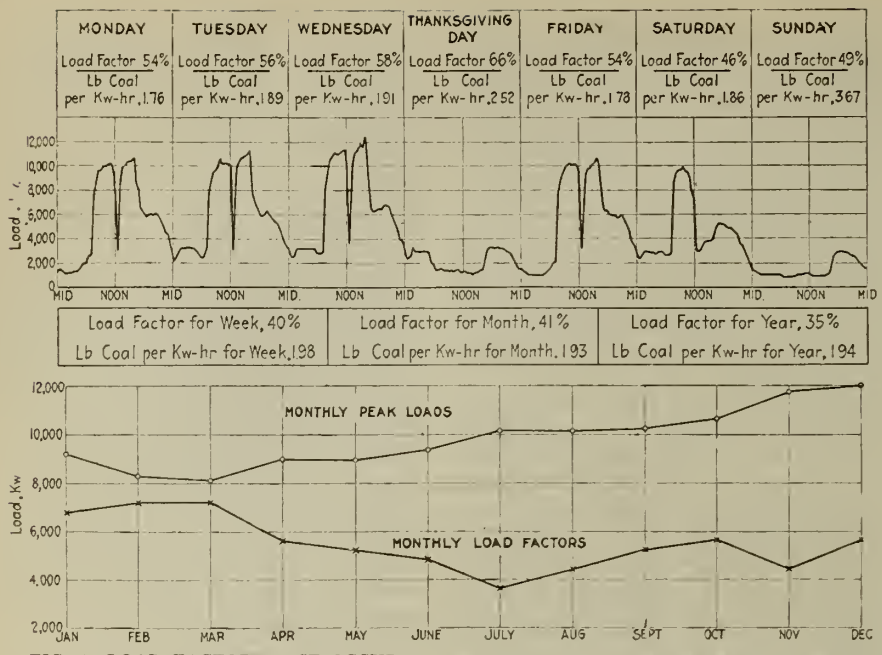

FIG. 4—LOAD FACTOR AS IT OCCURS FROM DAY TO DAY AND MONTH TO MONTH.

TABLE I.
OPERATING EXPENSES AS AFFECTED BY LOAD FACTOR.

	Operating Expenses, Cents per kw-hr.		
Annual load factor, per cent.	30	50	70
Fuel	$0.91	$0.85	$0.71
Labor for operation	0.10	0.07	0.06
Miscellaneous do.	0.04	0.03	0.03
Maintenance, mater. and labor	0.08	0.05	0.04
Total	$1.13	$1.00	$0.84

It is interesting to note, however, that the load factor for the year is practically the same in these two cases. This is due to the effect of the extremely low loads which obtain on Sundays and holidays. For these two conditions, illustrated by Fig. 3, having practically the same annual load factors, the better annual coal rate would be obtained with the one having the more favorable shape of load curve, that is, with the one in which the factory load predominates.

Fig. 4 shows how the load and load factor vary from day to day and month to month for a business in which factory load predominates. The beneficial effect of high load factor on Thanksgiving Day, for example, is much more than offset by the relatively small load on the station on that day. Note how the load factors for the week and for the month are practically the same. The load factor for the year is somewhat lower due to the variation in maximum demand throughout the various seasons. In general the better coal rates are obtained with the higher load factors, although this is greatly influenced by peak load, quality of fuel, and skill in operation, all of which are interesting subjects but beyond the scope of this discussion.

Discussion

In the extended discussion at the power session of the annual meeting, those whose remarks dealt more particularly with Mr. Junkersfeld's paper were Messrs. Charles Penrose and James T. Enes. Mr. Penrose stated that it is perhaps the foremost duty of the engineer to act as conserver of the natural resources and to obtain the greatest possible economy in power-station design. If this is true, he said, then instead of designing a power plant for existing loads it should be designed for abnormally high loads and then the load should be developed. This could be secured by a combination of circumstances and loads, including railroad electrification, street railway load and industrial uses. There has been secured, he said, within a short radius from New York City a load factor which at the present time, exclusive of Saturday, Sunday and holidays, has the high figure of 78 per cent.

Mr. Enes referred to the relation between the investment and load factor, which in turn depends upon fixed charges and operating expenses. Since we are now entering a new era of increasing prices, he said, it will be very difficult and perhaps impossible to determine such charges. We have in mind prices and the actual value based on the entire life of the plant. The problem is thus complicated because of the fact that we are now entering upon a period of increasing prices.

PALM OIL AS A FUEL

The world's supply of mineral oil is limited. At least, so say geologists, so that the experiments with vegetable oil as a motor fuel should be of decided interest. The oil used in these experiments has been palm oil, well known in the commercial markets as one of the most desirable ingredients of the nut-margarines. The tests have been carried on in Brussels, with a view of making use of palm oil, if practicable, as a motor fuel in the Kongo. The difficulty of transporting mineral oil to the Kongo, and its high cost when delivered —about $1.40 per gallon—made the finding of a substitute a great desideratum. And, as palm oil was one of the products of the Kongo, and could be had there for about 20 cents a gallon, the reward for its successful adaptation was alluring.

The calorific value of palm oil varies from 75 to 80 per cent. of that of mineral oil; therefore, from one-fourth to one-third more must be burned to get the same power.

The experiments have proved that palm oil will work perfectly in a certain form of motor of a semi-Diesel type without any change, in the ordinary Kongo temperatures. In Belgium, however, where the winter temperatures are below the solidifying point of palm oil, an accessory is necessary to liquefy the oil. Further, in Belgian winter temperatures it has been advisable to start the motor with petroleum, and when it is well warmed up to substitute the palm oil.

The experiments have shown that palm oil burns completely, leaving no residue. So far the trials have been made chiefly on motor boats, but they are being extended to tractors and industrial motors. In July, 1920, the Belgian Ministry of Colonies initiated a prize contest for tractors operated on any of the vegetable oils produced in the Kongo. Only one contestant appeared—an evidence of the lack of research along this line.

With the passing of petroleum, an eventuality already being discounted by the geologists, the practically unlimited production of vegetable motor oils may easily become one of the important industries of the near future.

VICKERS-PETTERS CATALOGUE

We have received from Messrs. Vickers, Petters, of Ipswich Works, Ipswich, England, their very well-illustrated catalogue, describing their semi-Diesel stationary and marine engines. These engines are made in sizes from 10 H.P. to 450 H.P. and they are designed to run on a great variety of fuel oils, and are equipped with a special starting device which enables them to start up from cold in a minute. A special arrangement of fuel injunction is used when the engine is running light, which enables it to run for long periods on no load or light load without misfiring. The catalogue describes the engines in great detail, and with plenty of illustrations. There is a page of the booklet devoted to hints to overseas buyers which should be carefully perused by any intending purchasers in this country. The name of the firm is of course sufficient guarantee of the workmanship put into these engines.

Jardine and Company, Canadian representatives for the American Manganese Bronze Company, have removed from their old offices at 285 Beaver Hall Hill into more commodious quarters at 180 St. James St., Room 102.

Explosion In High Pressure Air Line*

Explosion Ruptured Steel Pipe That Had Test Pressure of 2,500 lbs. Per Square Inch. Pipe Was Supplying Air to Compressed Air Locomotives at About 1,000 lbs. Per Square Inch

By E. D. GARDNER, Mining Engineer

AN explosion occurred in a high-pressure compressed-air line in October, 1920, at an Arizona copper mine. The explosion was unusual, and nothing had been noted by the plant operators to indicate the possibility of such an occurrence. The mining company uses compressed-air locomotives to haul about 4,500 tons of ore per day from the stopes to the pockets at two hoisting shafts. The ore cars hold five tons each, and are pulled in trains of 20 cars. It is necessary to charge the locomotive with compressed air at both ends of the trip. The air is conveyed from the compressors at the surface to the distributing points underground in special high-pressure four-inch steel pipe that was tested to withstand 2,500 pounds per square inch before being installed. The air is delivered to the locomotives at a pressure of 1,000 pounds per square inch. There are no receivers in the system.

The air for running the locomotives is compressed by one three-stage and two four-stage compressors which have capacities of 600 and 300 cubic feet per minute, respectively. These machines are operated by electric power, and are in an end of the main compressor building in which air is compressed to supply the air drills in the mine. Whenever the demand decreases, as at the noon hour, one or more of the compressors are shut down. On this particular occasion, at the end of the noon hour, one of the operators was approaching the high-pressure compressors to start the two smaller machines that were not running, when the explosion took place under the floor a few feet ahead of him. The man was knocked down and received some superficial cuts and bruises, but was not seriously injured. The floor was torn up, the side of the building blown out and holes knocked in the roof some twenty feet above. The explosion was immediately followed by a fire which was quickly put out by the plant operators with hand fire extinguishers.

At the time of the explosion the 600 cubic foot compressor was running alone, and the pressure in the system at the machine registered 1,040 pounds per square inch. On examination it was found that two 8-foot sections of pipe, about ten feet apart, were completely ruptured into twisted fragments; the rest of the pipe line apparently was not injured. The destroyed sections were in that part of the pipe near the large compressor and above the connection from the two smaller machines. It is not definitely known what caused the explosion. Explosions in other compressed-air systems have taken place, and, although of rare occurrence, have caused loss of life. Such explosions are not confined to high-pressure installations, and several have occurred at plants compressing air to one hundred pounds per square inch, or less. Explosions of this nature are not to be confused with the rupturing of compressor cylinders from excessive air pressure caused by discharge valve being closed.

A number of theories have been advanced to account for explosions in air lines, but there is not enough evidence to state positively that any one condition is responsible, and it is possible that there are a number of contributory causes. To obtain a gas explosion, two conditions are necessary; first, an explosive mixture, and, second, something to set it off. Enough oil must be fed into the cylinders of an air compressor to lubricate properly the moving parts, and in order to insure this an excess is used which may accumulate somewhere in the system. When oil is fed into the cylinder it is partly vaporized by mechanical action of the air. The quality of the oil used has an important bearing on the operation of the compressor, and is probably the most fruitful cause of explosions in receivers or air lines.

Apparently all cylinder oils are carbonized to some extent in the compressor cylinder, and, if the poorer grades of cylinder oil or those not adapted for the purpose are used, large deposits of carbon may accumulate in the air lines or receivers. This carbon is inflammable, becomes oil soaked, and is always a source of danger. Heated air from the compressor may cause the carbon to burn and thus vaporize the deposited oil in sufficient amount, together with any coming from the compressor, to form with the compressed air an explosive mixture. This mixture may then be exploded by the hot air, or, more likely, by a glowing point of carbon.

The temperature of the air in air compressors increases with the ratio of compression. The temperature at the end of the piston stroke in a single-stage machine, compressing to 100 pounds per square inch, is 425° F. above the intake air. In a 100-pound two-stage compressor with no intercooling, the increase of the air temperature is 180° for each cylinder. The final temperature of the air at the discharge end of the last cylinder of a three-stage machine compressing air to 1,000 pounds per sqaure inch, would be about 1,280°, if the air enters the compressor at 60° and no heat is lost by radiation.

The flash point of a series of paraffin-base compressor oils listed in a pamphlet issued by the Ingersoll-Rand Company varies from 375 to 500°, and the firing point from 425 to 575°. The flash point of a series of compressor oils with asphalt base varies from 305 to 375°, and the firing point from 360 to 404°. It will be noted there is only a small margin between the temperatures generated in the cylinders and the flash and the firing point from 360 to 404°. oils. Under high pressure the flash point would be lowered. Even if the oil vapor would not explode at the firing point, as held by some writers, an oil accumulation may start to burn which in itself might supply sufficient heat to cause an explosion. It seems likely, also, that an explosion in air lines could be brought about by the compressors being out of adjustment and the heat in the compressed air building up to a dangerous point.

Leaky valves in compressors are dangerous, and are held by some compressor men as generally being responsible for over-heating the air. In some types of compressors the discharge valve in the last-stage cylinder may not be tight, due to carbon deposits or some other cause, and a small part of the heated air may be drawn back into the cylinder with each stroke and be re-compressed. There is a difference of opinion, however, as to whether a leaky discharge valve can result in excessive over-heating of the compressed air. Theoretically, the air leaking back would cool to the temperature it was in the cylinder before being compressed, but it appears that, due to the churning motion of the piston and other heated moving parts, the temperature may rise sufficiently to vaporize the oil and cause an explosion.

Ordinarily the heat is effectively absorbed in high-pressure installations by a water intercooling system, but any stoppage or restriction of the water-flow would allow the temperature of the air in the compressor to increase rapidly to a dangerous point. In some types of compressors it is possible for the temperatures to build up when the air is not being used, by excessive unloading of the machine if a small leak occurs in the throttle unloading valve. With the compressor running and the valve closed, the intake side of the cylinder is in a vacuum. A small leak in the valve would permit some air to enter

*Railway and Locomotive Engineering

the cylinder, but it would be below atmospheric pressure. As the increase of temperature in the air varies with the ratio of compression, excessive heating is possible in this case. For example, under the above conditions, by assuming that the pressure in the intake side is 5 pounds per square inch and the compressor is furnishing air at 105-pound pressure, the ratio of compression would be twenty-one to one against seven to one under normal conditions. Most modern compressors, however, are equipped in such a manner that any air compressed under the above conditions is discharged to the outside atmosphere with no ill effects.

An inefficient oil trap may contribute to the explosion by permitting an unusually large amount of oil to leave the compressor with the air. Oil may burn in the pipe line and cause no damage, or a small explosion may take place with not sufficient force to rupture the pipe line, and carbon monoxide may be generated in the line. It is reported that men have lost their lives from carbon monoxide coming through the compressed-air line to the working face of a drift. To prevent explosions in air lines, the first consideration is to use the proper grade of cylinder oil, and, second, the compressor valves and intercooling system should be kept in good order. An aftercooler would appear desirable in high-pressure installations. Care should be taken that only fresh air be drawn through the intake of the air compressor.

COMBUSTION DEVELOPMENTS IN ENGLAND

Hard thinking arising out of the lessons of the war has brought about some unusually interesting developments in engineering abroad, according to Geo. E. Learnard, the president of the Combustion Engineering Corporation, who is at present in Europe in connection with the business of the newly formed International Combustion Engineering Corporation. He has sent the following interesting comments and observations on conditions in the combustion field in Europe.

"Although, when I left the United States, I felt that through our correspondence and affiliated companies I was well advised of the progress in European countries in the field of combustion engineering which field encompasses a more efficient utilization of raw fuel and labor saving devices wherever steam is made or fuel is burned, I am nevertheless surprised by what I have seen.

"I think engineers in the United States little appreciate the hard thinking on this side arising out of the lessons of the war.

"That countries such as England and France having no deposits of oil and, in the case of England, insignificant water power, should be devoting close attention to the extraction of oil from coal and to the employment of semi-coke for steam raising and for furnaces, was to be expected when we remember that one of the chief lessons of the war was that a country without oil is in a dangerous position.

"Another lesson arising out of the war, namely, the necessity of labor-saving devices to compensate for the reduced man power of the European countries has seemingly been taken to heart, and I have seen here certain devices toward labor saving in boiler rooms beyond anything known to me in the United States. Even under the present conditions of ample labor supply, due to slackness in general trade, these devices are being pressed into use, for commercialism is obliged to yield to the growing pressure of public sentiment as well as labor unions, toward the elimination of man-breaking and manual labor.

"As to the abstraction of oil from fuel, there is a considerable agitation in the country toward legislation making it compulsory that certain fuels should not be burned in their raw state, and that the light oils and certain tars should be extracted before they are used for furnace work or for steam raising. It is safe to forecast that in another ten years no highly bituminous coals in England will be burned in their raw state.

"The means placed at my disposal for investigating several new processes have convinced me of the rapid strides being made toward practical success in this field, but, unfortunately, since my information has been obtained in confidence, I am only permitted to mention one or two of these processes, or methods, in general terms.

"While oil from bituminous coals is being extracted in England by one large company in considerable quantities, and on a commercial basis, by processes akin to well-known American methods, the future, in my opinion, lies in two new inventions which are being experimented with and perfected in secret.

"One of these treats the fuel by internal heating in such a little space, and with such simplicity of mechanism, that the oil is extracted and the fuel reduced to semi-coke while it is progressing, steadily, by gravity from the main bunkers containing the raw fuel to the mechanical stoker hoppers. These mechanical stokers are specially adapted for receiving and burning the hot semi-coke from the interposed retort or distilling apparatus between the stoker hoppers and the main bunkers.

"The advantages of such a compact self-contained simple apparatus need not be seen to be appreciated. I am not permitted to elaborate or describe the detail of the apparatus more fully.

"The second method which I have investigated is of prime interest to those who are believers in the ultimate general employment of pulverized fuel for steam raising and furnace work.

"In this, the distillation of the fuel takes place while the fuel is being reduced to a powder, i.e., while it is being pulverized.

"Instead of this method for obtaining light oils and certain tars adding to the complication of pulverized fuel equipment, it appears, on the contrary, to simplify it, since the drier used in the ordinary pulverized fuel system disappears, and also since the powdered fuel, being in the form of semi-coke, enables it to be transported with a simplification of machinery or apparatus. Furthermore, this semi-coke is of such a character that it may be stored indefinitely without being affected by moisture or heat. The gases from the fuel in process of distillation are in part condensed to oil in the usual way, and the remainder carried to the furnace burners and injected into the furnace with the powdered semi-coke.

"Returning to the question of labor-saving devices in boiler rooms of the several called to my attention, decidedly the most interesting is an automatic ash conveyor for use in power stations, or wherever watertube steam boilers or metallurgical furnaces are employed.

"It was my pleasure to examine one of these conveyors at work, and I was indeed startled and astonished by its perfection of operation."

HAS FAITH IN THE ELECTRIC ROADS

Railway Engineer Quotes Figures That Show Where Savings Would Be Made

London.—The superior financial and operating advantages, together with the coal problem, will eventually compel the electrification of all Canadian railways, D. M. Morrison, chief engineer of the London & Port Stanley Railway, told the Rotary Club. Mr. Morrison declared that the electric locomotive is capable of working 24 hours a day seven days a week; that an electric railway can haul a third more freight than a steam road on this continent, and that maintenance of way charges are 50 per cent. less when electric locomotives are used. He stated that if all the steam roads in the United States were electrified the saving in coal annually would amount to 122,500,000 tons.

Trade Gossip

The briquette plant at Bienfait, Sask., which is subsidized by the Manitoba, Saskatchewan and Federal Governments, will begin manufacturing briquettes early in May, it was announced. The buildings are completed and only a little additional machinery remains to be installed. Several tests will be made before the briquettes are placed on the market. The plant was built at a cost of $500,000.

The H. Mueller Mfg. Co., Ltd., Sarnia, Ont., are contemplating the erection of an iron foundry.

A Course of Instruction for the Graded Certificate

The Various Types of Valves and Gears Met With in Stationary Practice—A Short Description of These Leading Up to the Method of Making the Adjustments Necessary for Good Results

By T. H. FENNER

IN the most recent articles we have explained fairly exhaustively the use of the indicator card, although, of course, there are further uses which we have not yet gone into. However, we believe that this is as far as will be necessary for the purposes of a course of this kind, but if readers express a wish for any particular question to be treated more fully, we will be glad to take it up.

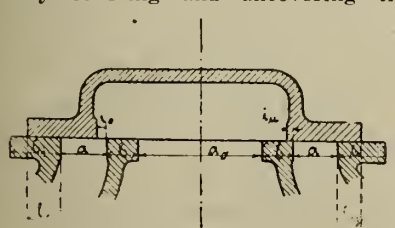
It is now in order to take up the more practical side of the steam distribution, in other words the setting of the valves, slide or otherwise, in order to get the best results. Before going into the actual valve setting, we will describe some of the types of valves in general use.

Types of Slide Valves

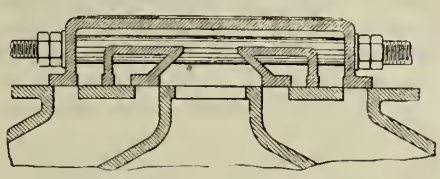
There is, of course, first of all the basic type or the common slide valve, in its original form without inside or outside lap, and in its later and more generally used construction, with both inside and outside lap. From this a number of modifications have been brought into being, such as the double ported slide valve, the triple ported slide valve, and the piston valve. There is the slide valve with the Meyer expansion valve fitted to the back, and the slide valve with a relief ring. All these forms have been introduced for the purpose of getting a large port opening with a small valve, thus reducing friction and weight of moving parts. The piston valve was introduced to get away from the heavy pressure on the back of the slide valve in high pressure engines, and is really a balanced valve. Piston valves are adopted largely in high-speed engines, and in the high-pressure cylinders of compound marine engines.

The Common Slide

The ordinary slide valve consists essentially of a casting with two flat edges and a raised centre. This raised centre forms an arch or cavity into which the exhaust steam is discharged from the cylinder, and communicates with a passage leading to the exhaust pipe. The flat edges perform the steam distribution by covering and uncovering the steam port, which is, of course, both inlet and outlet port alternately. Every engineer is familiar with this type of valve. It is simple, easily understood and widely used, but has its limitations. One of these is that the period of cut off cannot be made much less than half stroke without seriously interfering with the other function, as we explained in previous lectures, and another is that



THE D SLIDE VALVE



THE DOUBLE PORTED VALVE.

when the engine gets into the larger sizes, the slide valve tends to become unwieldy, and a cause of large friction losses. Thus it becomes necessary to adopt some modification to overcome these defects.

The Double Ported Valve

The double ported slide valve is a valve which has passages formed in it leading to the valve face, so that the steam, besides entering the port over the outside edge of the valve, can also enter through the back of the valve. The exhaust cavity remains the same as in the ordinary valve, but both ports can be put in communication with the exhaust cavity at once. The construction of the valve can be clearly followed from the illustration. The valve shown is in midposition, and therefore closed to both steam and exhaust. It will be seen that steam enters the port through the chamber from the back of the valve, and the inside bar acts in exactly the same way as the outside one. It is evident that with the same travel of valve practically double the port opening can be obtained that is possible with a single ported slide valve. These valves are sometimes made triple ported, but this is not so usual. The same factors govern the steam distribution as in the single ported valve, the only difference being in the increased port opening and quicker cut off. This does not mean earlier cut off, but a shorter length of time occupied in covering the port than would be the case with a single ported valve. This is easy to understand when we consider that the valve has only to move half the distance that a single ported valve would to either open or close the port. The shortened travel also decreases the friction, and for the same port opening a lighter valve can be made. This construction with a relief ring on the back of the valve makes a good working arrangement.

The Trick Valve

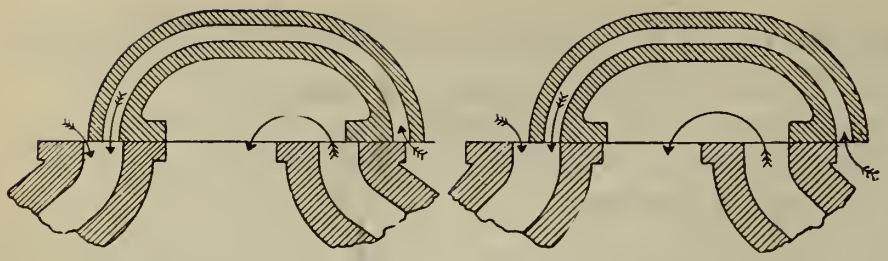
Another type of valve which was once largely used on locomotives is known as the trick valve. In this valve a passage is cored out from one side of the valve to the other. The valve is so arranged that when the valve is in mid position the passage just covers the valve chest face. When the valve opens to steam at one end, the passage at the other end overlaps the valve chest face, thus admitting steam from that end through the passage to the steam port, the effect being the same as achieved with the double ported valve. The passage has no effect on exhaust, which takes place over the inside edge of the valve in the usual manner.

The Piston Valve

The piston valve is a form of slide valve, and may be conceived to be a slide valve which is bent round to the form of a circle. If a piston valve is developed, that is laid out in flat form, it will be seen to comprise two flat edges with a cavity in the centre just like a common D slide valve. It has, however, one great advantage over the slide, and that is on account of its construction it can be made self balancing by admitting the steam in the centre, and exhausting over the ends, instead of admitting steam over the ends and exhausting through the centre. When steam is admitted in the centre, the pressure acts on the inside of the two pistons, thus placing the valve in a state of equilibrium, and the effort necessary to move it is only that due to the friction, and not to the weight. The friction is much reduced owing to the steam having no effect in pressing the pistons against the wall of the chest. Another advantage is that the glands have only low pressure steam to contend with instead of the boiler pressure, and in the case of a simple engine, the pressure on the stuffing box packing is only atmospheric. The piston valve is used largely in high-speed engines, both horizontal and vertical, and almost exclusively on the high-pressure cylinders of compound marine engines. The trick construction is occasionally used in piston valves, but not very frequently.

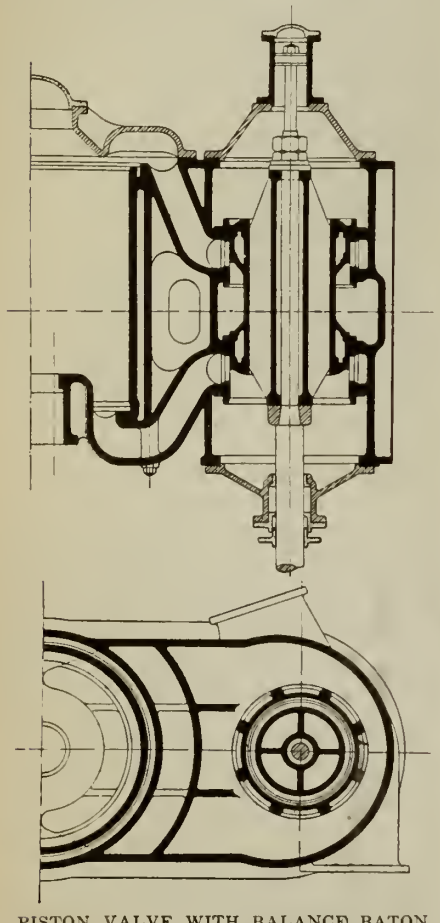
Quick Cut Off Valves

The necessity of getting a quicker opening to steam and a quicker cut off at an earlier point led to the introduc-



THE TRICK VALVE

tion of different forms of valves and gear. The principal of these is the Corliss, of the semi-rotary type. The Brown is a species of the poppett valve, while valves of the Wheelock and Macintosh Seymour type are really slide valves of the multi-ported variety, with special gear to get the quick opening and closing features. The effect of all these types of valves on the indicator card is



PISTON VALVE WITH BALANCE BATON

to give much sharper corners at the changing of the straight lines into curves, thus eliminating wire drawing of the steam at cut off, and a quicker drop of pressure at release. This tends to a greater area or card with the same steam supply. The Corliss valve is operated by an eccentric through suitable gearing, as is also the Wheelock and the Macintosh Seymour, while the Brown and poppett valves are operated by cams mounted on a cam shaft driven by gearing from the main crank shaft, like a gas engine.

The Corliss Valve

The Corliss valve is a semi-circular valve, its shape in cross section being of a T form. It is not connected solidly to the valve spindle, but is driven by a T head on the spindle which fits in a slot in the valve end. On the spindle there is keyed a bell crank, known as the steam arm, and one end of this is furnished with a die which engages with a hook, this hook being operated from the wrist plate by means of a connecting link. The other end of the steam arm lever is connected to the dash pot rod, which pulls the steam arm back rapidly after the hook disengages with the die on the other end of the arm. The point of disengagement is decided by the position of a loose cam also mounted on the valve spindle, and operated by a rod from the governor. Cut off can be set at any point from about one-eighth stroke up to half stroke by means of the governor rod. There are four valves on each cylinder, two steam and two exhaust. In many engines the exhaust valves are driven by a separate eccentric, thus making adjustment of the steam valves entirely independent of the exhaust. In other arrangements all four valves are driven by one eccentric, which operates a wrist plate to which all four reach rods or links are connected. The diagram illustrates quite clearly the construction.

The Wheelock Valve

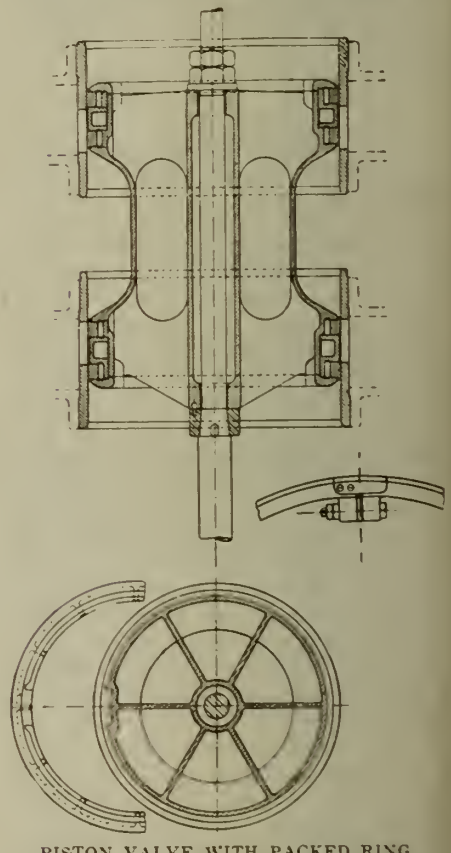
This valve is of the gridiron type, or multi-ported slide valve. The valve is operated by a knuckle joint, which is driven by rods attached to a link and wrist plate. Dashpots are used to give the quick cut off feature, and the governor determines the point of cut off in a similar manner to the Corliss gear. A feature of this valve is that both valve and seat are carried on a taper plug casting, which can be removed bodily from the cylinder for repair when necessary.

The Macintosh Seymour Valve

The arrangement built by this firm is somewhat different to any of those just described. The four-valve feature is adhered to, but in addition to this there is a riding cut off valve on the back of the main steam valves. The main eccentric operates the main steam and exhaust valves while the cut off valves are operated by an eccentric which is driven by the flywheel governor. There are no dashpots in connection with this gear, but the effect of the various links which connect the valves to the eccentrics gives the quick opening and closing required. These engines can be adjusted within very fine limits, and practically any kind of card that the operator wishes to get can be obtained by a little manipulation.

The Meyer Expansion Valve

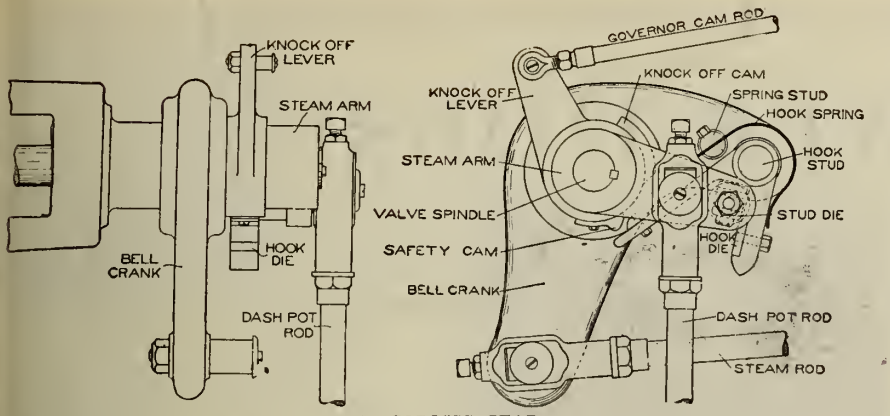
The Meyer expansion valve is a means adopted to get an early cut off with the ordinary slide valve, and consists of two flat plates made to work on the back of the main slide valve. The ports on the main valve are cut right through the valve, and the expansion valve governs the admission of steam to the ports of the main valve. The two plates can be drawn closer together or moved further apart by means of a right and left hand screw which passes through both plates and the distance these plates are apart determines the period of cut off. These valves will be found largely on steam cylinders of pumping engines, air



PISTON VALVE WITH PACKED RING

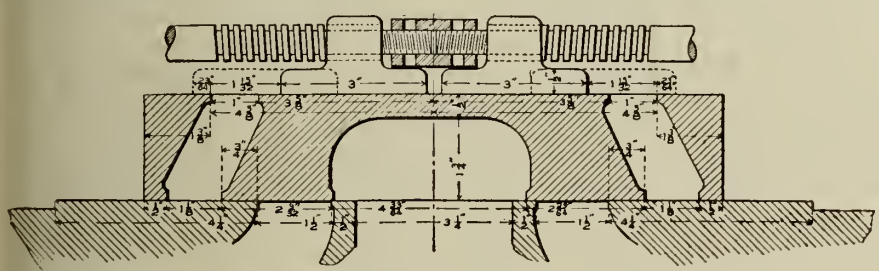
compressors, etc., and have the advantage of giving speedy adjustment from light load to a heavier one. They have the effect of adding to the friction, and need another eccentric to drive them. The eccentric to drive the expansion or cut off valves is set 90 degrees in advance of the main eccentric.

The foregoing covers the most generally used valves in the stationary field, and we can now give some thought to the setting of the various types. There is generally speaking not much difference in the methods employed to



THE CORLISS GEAR.

t any kind of valve, and furthermore ere is nothing excessively difficult out the operation. The motive power practically all the valves in general e is the eccentric, and if this is cor-ctly placed the fundamental require-ent in valve setting has been achieved.



THE MEYER VALVE.

he further adjustments are small and asily determined, both in the ordinary ide valve and the drop cut off valves. he first job therefore is to determine ie correct position for the eccentric ith reference to the crank, and to do iat we must be able to place the engine n the dead centre at either end with recision and certainty.

POWDERED COAL.

A paper that is considered to be of special value and timeliness was read ecently before the Providence Engineer-ig Society on the "Development in owdered Coal Burning" by H. D. Sav-ge, a member of A.S.M.E., A.I.M. & I.E., who is recognized to be an author-y on this subject.

Mr. Savage based much of his discus-ion on Rhode Island graphitic anthra-ite coal, using it as an instance of nferior fuel that was being made of arge commercial value through the pul-erizing process. The author of the aper is one of the experts of the ombustion Engineering Corporation on his subject, and is credited with having uch to do with making the advantages f pulverized coal known to the engin-ering world.

After a brief review of some of the istory of pulverized fuel, Mr. Savage in his paper takes up the Rhode Island deposit in showing where pulverization solves a difficult question.

The paper says in part:

"In the coal reserves of the United States the supply of Rhode Island graphitic anthracite is estimated at about 1,000,000,000 tons. Think of the enormous economic possibilities presented by the development of this deposit as a substitute for the very costly imported product—an accomplishment by no means imposisble of achievement.

"The Geological Survey, however, has not in the past taken a very optimistic view of this possibility. To quote from Professional Paper 190-A:

" 'The Rhode Island anthracite region, although known since 1760, is of little economic importance, for the coal has never been mined for a long period on a commercial scale, and, judging from its composition and the metamorphism of the surrounding rocks, it seems doubtful whether it will ever have more than a local value, if it is worked at all.'

"Assuming, however, that modern methods of mining have made the recovery of this coal possible on a commercial basis, there would seem to be no further obstacle to its use as an industrial fuel of merit.

"The inferiority of Rhode Island graphitic anthracite as compared with Pennsylvania anthracite when burned by the ordinary methods is due to its physical structure and the nature of the ash content. The only difficulty met in burning this graphitic coal in ordinary methods is that the ash will not free itself as combustion progresses. The coal makes a very brilliant fire for a short space of time, but the lump soon becomes surrounded with ash and is snuffed out. When burned in suspension in pulverized form combustion is, of course, instantaneous, and this trouble does not exist. The elimination of this one difficulty, therefore, makes it a thoroughly reliable and usable fuel. This assertion is based on very meagre information, to be sure, as the only test which we ran on this coal covered a period of only four hours and some four tons of coal. This test, however, clearly indicates that in a correctly designed plant there would be no difficulties encountered when burning this fuel in pulverized form. Figures covering the short test run are given herewith, as is also an analysis of the coal. There was no attempt made to run a boiler test, but simply to establish for our own satisfaction the fact that this fuel was of value, and that it could be burned under proper conditions.

"The low efficiency might be accounted for by the fact that this test was run in the early days of our development, and on an installation which was purely experimental, and which has since been abandoned for a more efficient type of furnace construction. However, since this test we have been prepared to make an installation under definite guarantees, but there seems to be but little interest in the development of this native product, which appears to us to have vast possibilities.

"The best results in burning anthracite of any kind are obtained when a constant rating can be maintained, as a high temperature in the surrounding refractories is a factor in securing desired results. It will not be found a satisfactory fuel for low ratings, or where the boilers are banked any considerable length of time, except in special cases, where the plant is designed for that particular service."

PROPERTIES OF METALS

An investigation into the properties of white metals for bearings has recently been carried out by the Bureau of Standards. It was found that tin-base alloys maintain their strength properties better at elevated temperatures than do those containing lead. However, the yield point or ultimate strength of a high-grade babbitt at either 25 deg. or 75 deg. Cent. is not affected by lead admixtures up to 3 per cent. Prolonged heating lowers the strength of lead-base alloys much more seriously than it does that of tin-base alloys. The yield point of a tin-base alloy was not affected by heating for six weeks at about 100 deg. Cent., but the yield point of a lead-base alloy was lowered by only two weeks' heating at the same temperature.

Doing a Good Work

IT is the custom of a good number of firms engaged in the manufacture of power plant apparatus and accessories to have lantern slides prepared illustrating the installation and use of their product. These slides are made available to engineering societies or technical schools for educational purposes, and serve the very useful purpose of enabling the engineer to acquire a knowledge of the different equipment that is available. This is good for the firm and instructive to the engineer, and it is also of benefit to the plant owner. The more engineers that can be made familiar with the principles and methods of operation of different kinds of equipment, the better for the men themselves and the men that employ them. The firms which manufacture the apparatus have the benefit of knowing that their equipment will get a fairer show if installed in the plant of an engineer who has already been made familiar with it through the medium of illustrated lectures. Makers of engineering specialties know only too well that their installations have often proved unsatisfactory not through any fault of their own, but from lack of interest and sometimes pure ignorance of the men who are responsible for their functioning.

The work being done by these firms is a good one for all concerned, and we hope more and more of them will take this means of acquainting the stationary engineer with the merits of their products. This is altogether apart from any advertising value the slides may have, for we believe that these slides are lent by the firms who own them without any other idea than to help out the engineers who are so often their clients. If they do gain some little advertising value, no one would be churlish enough to object. The larger good they are doing justifies them.

The Higher Standard

THE chairman of the Board of Examiners for Ontario, speaking at the annual banquet of the Toronto Lodge, C.A.S.E., spoke of the hopes and aims of the Board in raising the standard of stationary engineer in Ontario. Mr. Brown alluded to the Board of Trade certificate, and pointed out that it was a guarantee practically all over the world, and he wished to eventually raise the standard of the Ontario certificate until it too would be the best evidence a man could have of his ability. This cannot be done all at once, and at the beginning allowance has to be made in many cases, but the examinations will be gradually stiffened up as the engines in general get better educated technically and more fit to pass stiff theoretical examinations.

We believe with Mr. Brown that the standard of the examinations should be gradually increased until it is a real test of a man's ability both theoretically and from the point of view of experience. That is the function of an examination, but it does not, as some people imagine, stamp every one that passes it with the hall mark of standardization. We mean to say that you can take half a dozen men and set them down at the same examination board. They may all pass, and pass with equal marks, but that does not make them all equally capable in their work. They may each have the same amount of technical knowledge, and each have the necessary amount of experience to help out that knowledge, but one of the six will be a much more valuable man than any of the others, and there will be varying degrees between them all.

The fact remains however, that each one has passed a test which shows that he has a certain minimum amount of fundamental knowledge of his business, and a certain length of time has been spent at it. The higher the standard of the test, the less chance there is of the weak men passing . who may bring the whole thing into disrepute.

A Square Deal

IN another page of this magazine we publish a proposed form of contract to govern the purchase of coal as between buyer and seller. The form has been drawn up by the National Association of Purchasing Agents, an association that includes Canadian representation. There has long been a need of a standardized form that would protect the purchaser from the inconveniences and delays due to alleged car shortages, and real car shortages, inferior quality of coal, and all the other annoyances which the coal purchaser has had to put up with in the past. The form includes a statement of the approximate analysis of the coal contracted for, thus affording a definite standard for the quality of coal delivered. Weights are to be governed by the actual railway weights at the point of shipment from the mines. We do not notice any provision to protect the purchaser against loss by the way, which is sometimes considerable, depending on the kind of car the shipment is made in. On the whole, the form seems to be a fair deal to both parties, and there is, of course, nothing to prevent special clauses to govern special cases being put in. Very close limits as to description and analysis can be exacted by the purchaser, and should be used to protect his interests.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

BORING AIR CYLINDER

Question.—Will you please answer the llowing question: In what condition ould an air cylinder be left in, after boring, smooth or rough, and give asons?

Answer.—Generally speaking, if the linder liner or wall is of a good gray ose-grained iron, that is a hard iron, should be finished as smooth as is posble, because with a metal of that kind e wear will take place on the piston ngs sooner than on the cylinder wall. is the practice in some cases to leave e cylinder slightly rough, and allow e piston rings to wear the tool marks t of the liner. The rings are made ersize, so that when the cylinder is orn smooth they will be large enough be tight. As a rule, the metal of the linder should be harder than that of e rings, as it is a much easier matter fit new rings than to rebore a cylinr. Leaving a cylinder rough after rning is apt to score the rings during e wearing down process, and we should ways recommend the cylinder being nished smooth, and the rings made a od fit to start with.

MOUNT OF CIRCULATING WATER

Question.—A condenser on a steam engine is 6 feet long and fitted with 600 bes 6 feet long and ⅝ inch outside iameter. We wish to use the lake water r circulating purpose and would like to now how many gallons of water it will ke to keep 25 inches of vacuum?

Answer.—If you wish to maintain 25 ches vacuum that means that the temerature of the hot-well water will be bout 120 degrees. The engine is given s 250 horsepower and in the absence of ny figures we can assume that the team consumption is about 20 pounds er i.h.p. per hour. That would be ,000 pounds steam per hour. The total eat of that steam would be at 25 inches acuum 1,115 B.t.u. and the latent heat ,021 B.t.u. We can assume that the tent heat alone is given up to the conensing water, the temperature of the ondensate being that of the hot-well. Ve have then 1,021 x 5,000 pounds or ,105,000 B.t.u. per hour to be given up the circulating water. If the temerature of the circulating water is aised from an initial temperature of ay 60 degrees to 110 degrees, that is 0 B.t.u. per pound condensing water, we have 5,105,000 divided by 50, which is 102,100 pounds water per hour or 10,210 gallons. Of course, if the initial temperature is lower the quantity required is less. The amount given agrees closely with figures of recognized authorities, who give with circulating water at 60 degrees and vacuum at 26 inches from 17.5 to 21.9 pounds water per pound of steam condensed. In this case we have 5,000 pounds steam per hour condensed and 103,100 pounds water, which is 20.4 pounds water per pound of steam.

DUPLEX PUMPS

Question.—What makes a duplex pump short stroke on one side? Water not hot enough to form a vacuum. When cylinder cover is taken off water end, water still remains in chamber.

Answer.—The usual cause of a duplex pump short stroking one side is a leaky suction valve, though, of course, it may be due to the valve gear not being properly set. In the ordinary duplex pump, when the valve arms are hanging vertically from the bracket, the valves should be just covering the ports, or in other words, in mid position. We do not understand the latter part of the question in the form it is given. Please make this clearer.

BOILER HEATING CAPACITY

Question.—Kindly inform me how many cubic feet one boiler horse power will heat?

Answer.—I presume you mean the quantity of cubic feet of air, by your enquiry as to quantity of cubic feet one boiler horse power will heat.

One boiler horse power is the evaporation of 34.5 lbs. water per hour from and at 212 degrees F. This is $34.5 \times 966 = 33{,}327$ B.T.U. 1 cubic foot air heated from 0 to 70 requires 1.25 B.T.U. Then you could heat 26,661 C.F. air per hour from 0 to 70, or a room about 65x20x20.

One cubic foot water contains 62.5 lbs., and to heat it from 32 degrees to 162 degrees would require $62.5 \times 70 = 43{,}752$ B.T.U. Therefore, 1 B.H.P. would heat 7.6 lbs. water 70 deg. per hour.

Boiler horse power is like indicated horse power, a rate of doing work, and it would be better to say that so many cubic feet of air could be heated so many degrees by so many B.T.U. regardless of time.—Editor.

Progress in New Equipment

A NEW HIGH PRESSURE DAMPER REGULATOR.

A new hydraulically operated damper regulator, suitable for boiler pressure up to 250 pounds, has recently been developed by the Atlas Valve Company, 282 South Street, Newark, New Jersey. It is designed to automatically regulate the steam pressure on high pressure power boilers.

The cross-sectional view of this regulator shows all details. The operating water, under pressure, enters the regulator through the inlet A and, as indicated by the arrows, passes to the pilot valve, then to the bottom of the control cylinder through port D. It also passes to the control cylinder on top of the piston through pipe E into the hollow piston stem and into the control cylinder through holes F.

The pilot valve stem I is of spool form with the upper head passing over port D, which when above the port permits the water to pass into the bottom of the cylinder, and when below the port permits the water to escape from the bottom of the cylinder into outlet C.

The area of the top of this piston is reduced by an amount equal to the cross-sectional area of the piston stem, whereas the area of the bottom of the piston is larger. We therefore have two opposing forces pushing against opposite sides of the piston, the constant pressure acting against the lesser area on top of the piston tending to force it down, and the variable pressure from the pilot valve tending to push it up. Therefore, when pressure is admitted to the bottom of the cylinder the piston is forced up, and when the pressure is permitted to escape from the bottom of the cylinder, the constant pressure forces it down.

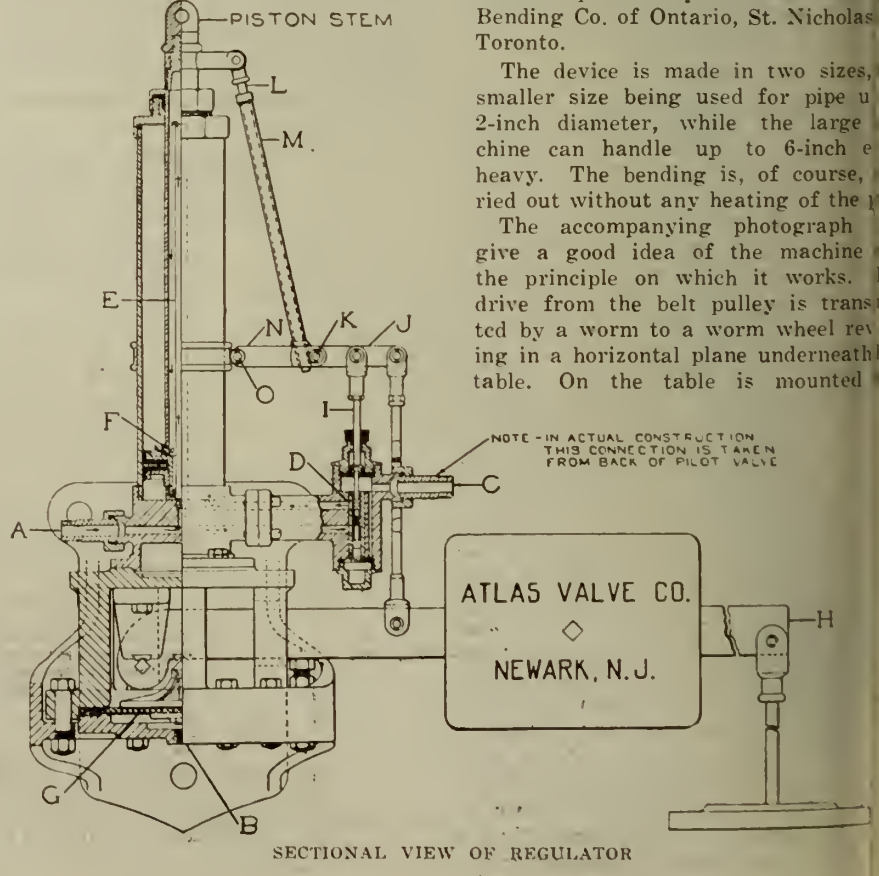
The Compensating Attachment.

When the steam pressure under diaphragm G is sufficient to raise lever H, the pilot valve stem I is pulled up by lever J, swinging on axis K; this permits the water to pass into the bottom of the control cylinder and force the piston up.

As the piston moves up rod L is pulled upward in sleeve M, which is rigidly attached to lever N, swinging on axis O. As the point where rod L is attached to the piston stem travels in a straight line, the angle at which sleeve M stands is lengthened, and to meet this longer angle sleeve M must swing outward, which depresses axis K on the end of lever N. This pushes pilot valve stem I down, so that the upper head of the stem covers port D, and shuts off the water supply to the bottom of the control cylinder, which checks the upward travel of the piston.

When the steam pressure falls, lever H lowers and pulls pilot valve stem I down, so that its upper head is below port D. This permits the water in the bottom of the control cylinder to escape into outlet C, which allows the constant pressure on top of the piston to force the piston down.

As the piston moves down rod L, sliding into sleeve M, shortens the angle at which sleeve M stands, and to meet this shortened angle sleeve M must swing inward, which raises axis K, and pulls pilot valve stem I up so that the upper head of the stem covers port D, and shuts off the water discharge from the bottom of the cylinder, which checks the downward travel of the piston.



SECTIONAL VIEW OF REGULATOR

The importance of the compensating attachment cannot be overestimated as it acts as an intermediary medium to counteract the movement transmitted to the pilot valve by the steam pressure under the diaphragm, which balances the position of the damper on intermediate pressure changes, and permits the damper to be fully opened or closed only on extreme boiler pressure variations.

This regulator will be known as "Victor No. 3." Victor No. 1 is made for low pressure heating boilers; Victor No. 2 is for medium pressure power boilers.

AN INTERESTING PIPE-BENDING MACHINE

The problem of bending wrought iron pipes to various degrees and getting the bend without distortion of the pipe has always been an interesting one. Many devices have been introduced to achieve the desired result, and we recently had the opportunity to see one of these at work. The machine in question is manufactured and operated by the Tube and Pipe Bending Co. of Ontario, St. Nicholas St., Toronto.

The device is made in two sizes, the smaller size being used for pipe up to 2-inch diameter, while the larger machine can handle up to 6-inch extra heavy. The bending is, of course, carried out without any heating of the pipe.

The accompanying photograph will give a good idea of the machine and the principle on which it works. The drive from the belt pulley is transmitted by a worm to a worm wheel revolving in a horizontal plane underneath the table. On the table is mounted

BENDING AUTOMOBILE EXHAUST PIPES.

form for bending, and these forms are, of course, made to accommodate the various sizes to be bent. The pipe to be bent is placed in the jaws of the vise and is run through between the form and vise the necessary distance to form the bend. The mandrel carried on the table is then run into the pipe just as far as is necessary. A series of stops on a quadrant under the table can be set to any number of degrees that may be required. When the pipe is set, the operator presses a pedal, which thows the head carrying the mandril into gear with the revolving worm, thus turning the head and mandril, and, of course, the pipe, through the arc previously settled. When the stop is reached, the machine disengages automatically. The mandril, owing to the path described by the table, automatically draws out of the pipe as the bend is formed.

The machine can be used to put several bends in a pipe, and we saw a number of exhaust pipes for automobiles which contained no less than five bends. One great feature with a machine of this kind is that, once it is set, it can produce any number of absolutely identical bends. This makes it especially useful where large numbers of pipes must be bent to a uniform standard. We had an opportunity to examine some four-inch pipe which had been bent to about 60 degrees, and there was no sign of any wrinkles or distortion on the inner side of the bend. A large number of bends on extra heavy pipe for marine work were performed on the large machine during the shipbuilding activities recently, and were all passed by Lloyd's surveyors.

We understand this machine is fully protected by patents in Canada and the U. S.

A COMPACT POWER PUMP.

A very neatly arranged power pump is being manufactured by the Thomas Machine Shop, 339 King Street W., Toronto. The pump, as shown in the accompanying illustration, is mounted on a bedplate which carries all the necessary gear for driving. The driving pulley is keyed to the first pinion shaft, and the pinion is cut from the solid cold rolled shafting, thus eliminating any chance of worn keys or keyways. The spur gear is keyed directly on to the crank shaft, and is a heavy cast iron gear 6 pitch. The gear also forms one side of the disc crank, and the connecting rod bearing is of heavy bronze, working on the pin between the discs. The rod itself, as can be seen from the cut, is of extra heavy construction. The pump itself is made entirely of bronze, as is the piston and pump rod. A notable feature of the pump is the fact that the valves are all outside, and consist of four standard design check valves of the swing type. This not only ensures a long life for the valves, but makes the repairing of a valve a matter of minutes only.

The arrangement is very convenient for all purposes where small pumps are needed, and especially where the nature of the fluid to be pumped is corrosive. The pumps are made up to 4 x 4 inch. The piston and piston rod glands are packed with the usual hydraulic packing.

NEW POWER PUMP

PUMP GOVERNOR BULLETIN.

Having acquired sole rights to manufacture and sell Ideal pump governors, the Atlas Valve Company, 282 South Street, Newark, N. J., are now distributing their first bulletin describing this excellent governor—Bulletin No. 1—A, Edition No. 1.

The bulletin is unusual in that it is complete. It shows photographs of finished pump governors, shows cross-sectional drawings with all parts numbered, installation and operation are fully explained, it gives dimensions, and it also contains prices. The purchaser can therefore order directly from the bulletin without preliminary correspondence.

It includes descriptions of the Ideal pump governor for turbine or reciprocating steam driven pumps; for marine or stationary turbines; fire pumps, lubricating oil pumps, bilge pumps, fuel oil pumps, a pump governor equipped with an emergency control lever for saturated or superheated steam, and automatic shut-off pump governor which automatically shuts down a pump in case of accident to the pump discharge line; a relief valve for oil pumps accepted by the United States Navy for use on Navy vessels suitable for light or heavy oil under high or low pressure; and a high pressure hydraulic regulating valve suitable for pressures from 500 to 1,000 pounds per square inch. The Ideal pump Governor is approved by the National Board of Supervising Inspectors of Steam Vessels, and it is also approved by the Bureau of Engineering, United States Navy Department. Two pages of the bulletins are devoted to special type of Ideal governors for accumulators, for high pressure fire hydrant service to reduce the main pressure to a safe carrying hose pressure, for hydraulic pumping rams, and for pumps for low pressure salt or fresh water, acids, oil, ammonia, gas or air-line service.

A copy of the bulletin will be mailed to any reader of this publication upon request.

THE LARGEST COOLING TOWER

It is claimed that the cooling tower erected by the Dodge Brothers at their Detroit plant is the largest in the world. It is 146 feet long, 42 feet wide and 104 feet high. It is capable of cooling 18,000 gallons of water per minute from a temperature of 105 degrees to 85 degrees when the outside temperature is 72 degrees and the relative humidity is 69 per cent. With other atmospheric conditions the water will be cooled to within 25 degrees of the existing dew point with a minimum temperature of 45 degrees. The loss of water by evaporation under these conditions amounts to 5 per cent. The tower has been strongly built and is braced to be able to withstand a wind of 90 miles per hour.

The Operators' Point of View

THE PERPETUAL AIR COMPRESSOR.

The scheme that Mr. Nicholaides has devised from his air compressor undoubtedly looks well on paper. The fault being that it is based on a false premise, naturally, the conclusion is also false. It is not a question of how much energy was expended to produce a certain amount of compression, but of how much energy this compression will furnish when again expanded. Because a single air compressor (such as the one he describes) requires 172,800 foot pounds of energy to produce one cubic foot of air at 150 pounds pressure, it does not follow that he should lay claim to perpetual motion, because his arrangement will produce a cubic foot of air at 150 pounds pressure with a smaller expenditure of energy. It merely goes to show the inefficiency of the single air compressor. Quoting from Mr. Nicholaides' article, he says: "Suppose that we use back those eight cubic feet of air, compressed as we stated to ten atmospheres, viz.: as a driving force in another set, we will not obtain back the whole amount of the 172,800 pounds, as some power is lost on account of friction, produced heat, and other causes." Very good! Had he taken the trouble to figure out the amount of power he could get back from his one cubic foot of air, he would never have made any such claim as 200% efficiency. As he did not do it, let us do it for him. As he admits a loss of 30% in the last or eighth cylinder, we will not bother with that one, but simply use it as a reservoir holding one cubic foot of air at 120 lbs. pressure. Now, if we expand this down to atmospheric pressure we shall find out exactly how much work it will perform. Let us take this eight cylinder engine and, starting with one cubic foot of air at 120 lbs. pressure, allow it to expand back into cylinder number seven. Thus we increase the volume to two cubic feet and decrease the pressure to sixty lbs. This will give us an M.E.P. of 90 lbs. 90 x 144 gives us 12,960 foot lbs. of work performed in cylinder number seven. As it required 16,980 foot pounds of work to compress this cylinder full of air, we already have a loss of 4,320 foot pounds in the first stage of its expansion. Now let us try expanding it again. Allow the air to back up into cylinder number six. As the air is now three times the volume it will be one-third of the pressure at the end of the stroke. This gives us 40 lbs. and with an initial pressure in this cylinder of 60 lbs. gives us an M.E.P. of 50 lbs. 50 x 144 is 7,200, and this is the energy in foot pounds which we may obtain from this cylinder. The energy required ofr this cylinder was 8,640 foot pounds, so here we have a loss of 1,440 foot pounds, or one-fifth of the initial pressure required. To continue, expand this air down to its final expansion, and it gives us respectively these M.E.P.'s: 35 lbs. in the fifth, 19.5 in the fourth, 7 in the fifth, 3.6 in the sixth, and 1.1 in the last. The sum total is as follows: 1st expansion, M.E.P. 90 lbs., work performed, 12,960; 2nd expansion, M.E.P. 50 lbs., work performed, 7,200; 3rd expansion, M.E.P. 35 lbs., work performed 5,040; 4th expansion, M.E.P. 19.5 lbs., work performed, 2,808: 5th expansion, M.E.P. 7 lbs., work performed 1,008; 6th expansion, M.E.P. 3.6 lbs., work performed, 518; 7th expansion, M.E.P. 1.1 lbs., work performed, 158; the total work performed in foot pounds is 29,692, and as we did not do any work in the eighth cylinder, by subtracting the steam required for that cylinder from the total amount required to run the compressors (that is 59,918—21,600 equals 38,318) we can arrive at the figures necessary to find the thermal efficiency of the whole arrangement.

Thus we have: total energy required to compress eight cubic feet of air into one cubic foot — 38,318 foot pounds. Total energy obtained from one cubic foot of air, expanded to atmospheric pressure—29,692. Now, divide 29,692 by 38,318 and we get an efficiency of .77 approximately. This I think is sufficient refutation of the perpetual motion theory. There is no doubt that this arrangement of cylinders would give a much higher thermal efficiency than the single air compressor, but how it would compare with one of the larger compressors, which compound both the air and the steam, is a matter for others to take up. Suffice it to say, the mechanical difficulties in the way of constructing such an apparatus are almost insurmountable. To point out a few, I would ask: "How could the steam be regulated for pressure and timing?" "How would the air be cooled from one cylinder to another without having undue clearance space?" Then again, "How would initial cost and upkeep compare with a single stage compressor?"

What Mr. Nicholaides is trying to do is, apparently, to secure the hyperbolic compression of air by a hyperbolic utilization of steam power in a series of cylinders. Whether it can be done or not depends on experimentation. If it can be done, it will, undoubtedly, give a higher efficiency than the single stage compressor, but it would not give the efficiency that a gear-driven compressor will give. In conclusion I should like to say that I have used the figures on the diagram in all my calculations, so that even if these are wrong in the first place it will make no difference to the ultimate result. It stands to reason, that when air is compressed, a certain amount of work is performed, also there is a certain loss from friction steam condensation, heat generated by compression which can never be recovered in any way, but it takes more energy to perform this work than can ever be recovered from it again. One thing which we should thank Mr. Nicholaides for is for bringing so clearly to our notice the thermal efficiency of the single stage compressor and it is quite probable that through the instrumentality of his idea a much more efficient method of compression may be evolved. His idea is excellent and I wish him luck with it, though he will, most certainly, never get his compressor to run itself by the power it generates.

Reg. A. Woods,
Saskatchewan Provincial Hospital.
Battleford, Sask.

* * *

To Editor, Power House:

It appears to me that a revision of the figures on the sketch shown on page 30 of the March 5, 1921, "Power House" shows that the inventor of the device would be sadly disappointed in the performance of a pair of working models (if such were constructed and operated in comparison); the one model having a single steam cylinder as per the upper left hand corner of the sketch; the other having eight steam-driven cylinders as per the lower portion of the said sketch.

In making the computations one might use any one of a number of sets of formulae, but for convenience let us choose a simple one. Simple formulae, not the most precise, but sufficiently accurate for our purpose become—after exchanging some of the letters for others which I think will serve the present case

etter—

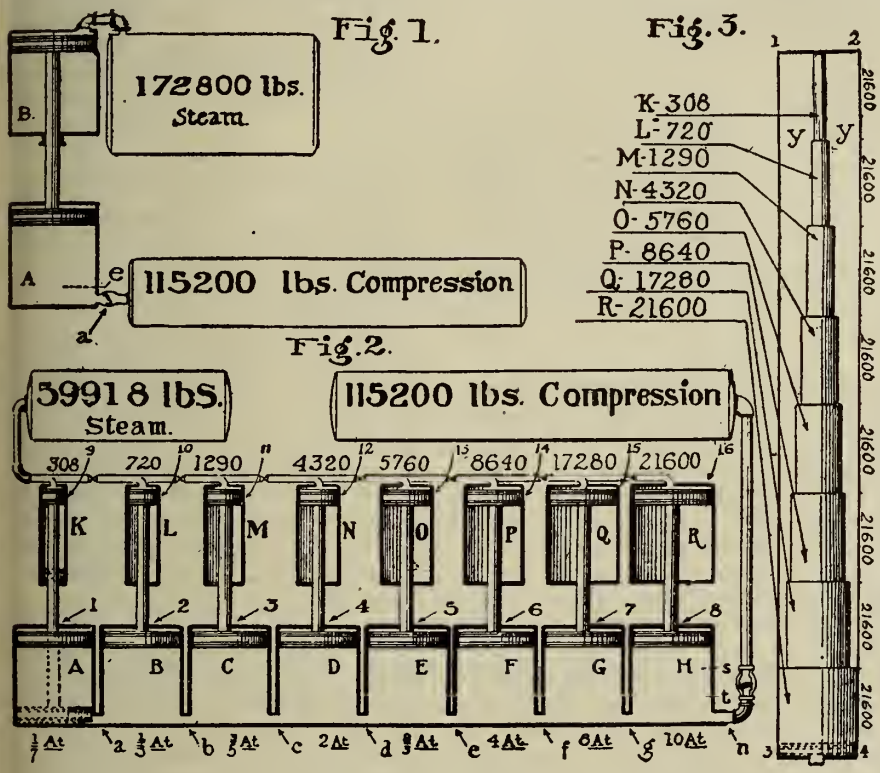
$A = \frac{M}{R}$; also $A = \frac{L}{R} - 1$; $R = \frac{L}{A+1}$;

$I = L - R$; $\frac{L}{R} = A + 1$; $\frac{L}{R} - 1 = A$.

When A = atmospheres pressure by he gauge.

A + 1 = atmospheres pressure (absolute).

L = total length of space between the iston and the farther end of the cylin-



ler when the piston is at one extreme nd of the stroke.

M = the distance the piston has moved orward.

R = the distance remaining between he piston and that end of the cylinder oward which the piston has been approaching.

For fair play the main thing is to, whatever set of formulae is used, use he same formulae and methods for each lass of device being compared. Also or convenience we will use decimals in omputing the atmospheres of pressure. We will also assume that in each case onstant temperature is maintained and hat there is no "clearance" nor leakage o be accounted for.

In the eight air cylinder machine and with—

Piston No. 1 down we have $\frac{M}{R} =$

1 ÷ 7 = .142 atmospheres pressure by he gauge.

Piston No. 2 down we have $\frac{M}{R} =$

2 ÷ 6 = .333 atmospheres pressure by the gauge.

Piston No. 3 down we have $\frac{M}{R} =$

3 ÷ 5 = .600 atmospheres pressure by the gauge.

Piston No. 4 down we have $\frac{M}{R} =$

4 ÷ 4 = 1 atmospheres pressure by the gauge.

Piston No. 5 down we have $\frac{M}{R} =$

5 ÷ 3 = 1.666 atmospheres pressure by the gauge.

Piston No. 6 down we have $\frac{M}{R} =$

6 ÷ 2 = 3 atmospheres pressure by the gauge.

Piston No. 7 down we have $\frac{M}{R} =$

7 ÷ 1 = 7 atmospheres pressure by the gauge.

Piston No. 8 down we have $\frac{M}{R} =$

10 atmospheres pressure before full stroke.

Total, 23.741, which multiplied either by 144 and by 15; or by their product, which is 2,160, we have 51,280.560.

The respective terminal pressures on the pistons are—

	(Calculated)	(Approx.) (gauge)
On No. 1	(206.72)	207 lbs.
2	(719.28)	720 "
3	(1,296.)	1,296 "
4	(2,160.)	2,160 "
5	(3,598.56)	3,600 "
6	(6,480.)	6,480 "
7	(15,120.)	15,120 "
8	(21,600.)	21,600 "
Totals	51,280.56	51,283 "

The difference in the totals being due to the difference between "calculated" and "approx." pressures given for pistons 1, 2 and 5. The total for the "calculated" column agrees with the total previously secured—51,280.56. As the strokes are each one foot long these would be foot pounds of energy exerted except for the fact that these figures are for terminal pressure instead of for mean pressure, which would be less.

It will be noticed that these calculations do not agree with the figures on the sketch since there the first three pistons and the last one are calculated to atmospheres by gauge, while the 4th, 5th, 6th and 7th are calculated to atmospheres absolute. Subtracting one atmosphere or 2,160 from the figures given in the sketch, for each of the four pistons last mentioned, brings them into accord with the figures given above.

For testing the formulae given above let us start with all the pistons up. We know then that L and R each equal 8 and that M and A each equal O; then the formula $A = \frac{M}{R}$ becomes $O = \frac{O}{8}$ and the others become respectively $O = \frac{8}{8} - 1$; $8 = \frac{8}{O+1}$; $O = 8 - 8$; $\frac{8}{8} = 8$; $A + 1$ (thus $A = O$) $\frac{8}{8} - 1 = O$.

With the first six pistons down we know that L = 8; M = 6; R = 2; and A is given above as 3.

Then $3 = \frac{6}{2}$; also $3 = \frac{8}{2} - 1$; $2 = \frac{8}{3+1}$; $6 = 8 - 2$; $\frac{8}{2} = 3 + 1$. $\frac{8}{2} - 1 = 3$. The same may be tried on each piston except No. 8, but with it the valve into the reservoir is supposed to open at a pressure of ten atmospheres gauge, thus preventing further accumulation of pressure. Hence our formulae do not fully apply then.

Now for the upper left hand corner of the sketch. It is there assumed that 144 × 15 × 8 × 10 = 172,800 foot pounds of steam power are required to compress 8 cubic feet of air to 10 atmospheres pressure, and this regardless of the fact that when the attached air piston starts at atmospheric pressure and that when it has reached mid-stroke the pressure against it is only 15 pounds per square inch or 2,160 altogether. To obtain a fair comparison with the other device we must calculate the piston pressures on this at eight points also, say at positions 1½ inches apart. Then at the beginning of the stroke the pressure is one atmosphere absolute or no pressure by the gauge. At a position 1½ inches

$$\text{therefrom } \frac{M}{R} = \frac{1\frac{1}{2}}{10\frac{1}{2}} = .142 \text{ at. gau.}$$

$$\text{At 3 inches } \frac{M}{R} = \frac{3}{9} = .333 \text{ at. gau.}$$

$$\text{At } 4\frac{1}{2} \text{ inches } \frac{M}{R} = \frac{4\frac{1}{2}}{7\frac{1}{2}} = .600 \text{ at. gau.}$$

$$\text{At 6 inches } \frac{M}{R} = \frac{6}{6} = 1.000 \text{ at. gau.}$$

$$\text{At } 7\frac{1}{2} \text{ inches } \frac{M}{R} = \frac{7\frac{1}{2}}{4\frac{1}{2}} = 1.666 \text{ at. gau.}$$

$$\text{At 9 inches } \frac{M}{R} = \frac{9}{3} = 3 \text{ at. gau.}$$

$$\text{At } 10\frac{1}{2} \text{ inches } \frac{M}{R} = \frac{10\frac{1}{2}}{1\frac{1}{2}} = 7 \text{ at. gau.}$$

At 12 inches it is discharging at 10 at. gau.

The total is 23.741 atmospheres and when multiplied by 144 and by 15, or by their product, which is 2,160, it becomes 51,280.56, just as was the case with the eight-cylinder air machine. The loss of power is mentioned as 30 per cent. At that rate the 51,280 becomes 35,896 and the figures are 51,280 and 35,896 instead of 172,800 and 115,200 as given in the sketch. If the compressed air were used again for power purposes the loss might be more nearly 50 per cent. than 30 unless uncommonly, I might almost say exceptionally, efficient machines were used.

In the above there appears to be an error due to calculating the 1½-inch sections of the 12-inch stroke at the same foot pounds value as though the sections were one foot long; but, since eight working strokes are required for compressing the stipulated eight cubic feet of air, and since $1\frac{1}{2} \times 8 = 12$, the figures given are obviously the same as though we had calculated each section at its true terminal value in foot pounds and then multiplied by the number of working strokes. Again, in the eight air cylinder machine we did not make sections for each cylinder nor piston pressure. This is because each of the eight cylinders constituted the parallel or equivalent of one section (during the eight working strokes) of the single air piston machine. We could make sixteen or more calculations for each machine but would be no nearer proving a gain of efficiency of one machine over the other. The adoption of stage air compressors is evidence that multi-cylinder machines, to a certain extent at any rate, may prove more efficient in practice than single cylinder machines; but they cannot attain 100 per cent. efficiency.

The main oversight in the sketch is, I believe, the assuming that the steam in the steam cylinder of the single air cylinder machine is working against a pressure of ten atmospheres during its entire stroke. The next is in assuming that the air compressed by the 308 pounds work on piston No. 1 of the eight air cylinder machine is compressed to ten atmospheres in the last cylinder without any further expenditure of work. In reality that air exerts a resistance against each of the remaining seven pistons and they in turn each expend a portion of work on it before it reaches the final pressure of ten atmospheres in the last cylinder.

Too often the man who invents something aside from the line of his own occupation, or for some purpose, the existing devices for which are not well understood by him, loses money.

J. McCormack.

* * *

Editor, Power House:

Cylinder A contains 1 cubic foot air at atmospheric pressure (14.72 at sea level, 30″ barometer), to compress that volume air to 10 atmospheres (or 132.3 pounds gauge pressure) and allowing 30 per cent. loss for heat, friction and other causes, we need a total pressure on steam

$$\text{piston of } \frac{132.3 \times 144 \times 130}{100} = 24{,}767$$

pounds, but we will only need this pressure at end of stroke and for 8 cubic feet $24{,}767 \times 8 = 198{,}136$ pounds. Now, the pressure in compressor cylinder is zero (or 14.7 absolute) at beginning of stroke and 132.3 at end of stroke, and it would only take enough steam to overcome friction to start piston on its travel. During the early stage of the stroke the steam piston has a slowly accumulating load to carry, while later on this load is multiplied very rapidly. Now in figuring out foot-pounds for an air compressor we cannot take the pressure at end of stroke, multiply it by travel and call it foot-pounds, which is what Mr. Nicholaides has done in his compressor No. 1, while in his compressor No. 2 he has figured his work (foot-pounds) in eight stages. The same could have been done in his first compressor, by taking one-eighth of the stroke at a time. Now he is wrong to start, which, of course, gets worse as he goes along.

Now allowing 100 per cent. mechanical efficiency (not possible) and isothermal compression, we would have a mean effective pressure in air cylinder of $\frac{132.3}{2} = 66.15$ pounds or in foot-pounds with 30 per cent. loss per cubic foot $= \frac{66.15 \times 144 \times 130}{100} = 12{,}383$ foot-pounds and for 8 cubic feet $12{,}383 \times 8 = 99{,}064$ foot-pounds.

An indicator curve for an air compressor, comprising 10 atmospheres, would (isothermal curve) be pretty near straight from 14.7 pounds (absolute pressure) to 147 (absolute) while the indicator curve for steam cylinder would be nearly constant as power at beginning of stroke would be stored in flywheel and helping to carry piston over the latter part of stroke. The writer has had occasion to take readings of a electric motor, belt connected to an a compressor, and only very slight varia tion was visible on the ammeter.

I do not see any need in going furthe with his calculation and then our learne friend from San Diego must have fo gotten Boyle's law when he says, "Th law cannot apply in stage compression I learned the law as: "The absolute pre sure of a gas varies inversely as i volume, at constant temperature." Th latter part he must have forgotten.

I sincerely hope this explains it. not, I have our editor's little note i last issue of the Power House as a excuse. My certificate of competenc as a stationary engineer is only thi class.

Ernest Quist.

UNIFORM COAL CONTRACT

For some time past the Fuel Commi tee of the National Association of Pu chasing Agents has been engaged i formulating recommendations for rea sonably uniform provisions in coal co tracts. The purpose of the committe has been to express its idea of a fa contract to be used for the purchase an sale of coal. To avoid overlooking im portant details and to prevent any bia in its suggestions, the committee co ferred with a number of leading pr ducers and wholesalers in the coal field holding a meeting for this purpose a the Hotel Pennsylvania, New York, o March 15.

The conclusions of the committee ar expressed in the form of contract at tached. It is believed that the form ca be advantageously used for most com mercial contracts for the purchase o coal, and where special conditions re quire special clauses these might be ado ed to the contract.

The form has been prepared simply a a convenience to the members of th National Association of Purchasin Agents and the trade, and is submitte by the committee for the use of thos whose requirements it will meet. It ha been carefully worked out to cover al general conditions and is particularl designed to prevent misunderstanding between buyer and seller such as aros from the loosely drawn agreements i effect last year.

The administrative council of the Fue Committee of the National Associatio of Purchasing Agents is as follows Chairman, E. H. Hawkins, of E. I. d Pont de Nemours & Co., Wilmington Del.; H. M. Mitchell, of Rome Mfg. Co Rome, N.Y.; J. E. Stuaffer, of A. M Byers Co., Pittsburgh, Pa.; R. M. Sedg wick, of Standard Chemical Co., To ronto, Ont.; H. M. Cosgrove, of J. H Markham, Jr., Tulsa, Okla.; H. L. Ogden of Gas & Electric Improvement Co. Boston, Mass.

In the preparation of the propose contract form the committee has had th guidance and advice of W. B. Symmes Jr., of New York, formerly solicitor fo the United States Fuel Administration

(This is contract form for coal recommended by the National Association of Purchasing Agents)

Agreement entered into this .... day of..... 19...., between.....

of ....., hereinafter referred to as Seller,

and ..... of .....
hereinafter referred to as Buyer.

The Seller hereby agrees to sell and deliver and the Buyer hereby agrees to purchase, between the ..... day of .....,

19.... and the ..... day of ..... 19....., the quantity and kind of coal and at the price hereinafter stated upon the terms and conditions herein contained, to wit:

QUANTITY ..... net tons

RATE OF SHIPMENT (approximately) ..... net tons per month

DESCRIPTION

Approximate Analysis

PRICE $..... per net ton of 2,000 lbs. f. o. b. cars mines.

POINT OF DELIVERY: f.o.b. cars mines.

TO BE SHIPPED TO .....

DESTINATION .....

ROUTING .....

KIND OF CARS PREFERRED .....

TERMS AND CONDITIONS

1. Invoices shall be paid on or before the ..... day of each month for all coal shipped during the preceding calendar month. Non-compliance with said terms of payment shall give the Seller the right to suspend further shipments until all previous shipments are paid for, and if in the judgment of the Seller the financial responsibility of the Buyer shall at any time become impaired and written notice thereof be given by the Seller to the Buyer, the Seller shall have the right to suspend further shipments until adequate security for payment hereunder is furnished by the Buyer. If such security is not furnished within thirty days from such notice, the Seller shall have the right to cancel this agreement.

2. All settlements shall be governed by the actual railroad weights ascertained at the usual points at which railroad shipments from the mine or mines producing the coal shipped hereunder are weighed.

3. Strikes, fires or accidents at the mine or mines where the coal sold hereunder is produced, embargoes, shortage of car supply or other similar occurrences beyond the control of the operator of such mine or mines which prevent or interrupt the shipment of such coal, shall excuse Seller's failure to ship hereunder during the continuance of such occurrence, **provided**,

(a) the Seller is the owner or exclusive sales agent of the mine or mines at which the coal sold hereunder is produced, or prior to or simultaneously with the execution of this agreement has entered into a written contract for the purchase of a sufficient quantity of coal from such mine or mines to fulfill the obligations of the Seller under this agreement;

(b) the name of the owners and location of such mine or mines is stated in this agreement;

(c) the Seller gives the Buyer written notice within five days after such occurrence of the exact nature, extent and probable duration thereof with sufficient detail to enable the Buyer to verify the same;

(d) the total available tonnage of said mine or mines during prevention or interruption of shipments as aforesaid is applied pro rata on all contracts then in force or any renewals thereof for the output of such mine or mines exclusive of contracts or sales made after such occurrence;

(e) Shortage of car supply shall not excuse failure to ship hereunder if at the time of such failure there are in force contracts for the sale of more than the rated output of such mine or mines based on the car rating given such mine or mines at the date of this agreement by the railroads on which the same are located.

4. In case of strikes, fires, accidents or causes beyond the control of the Buyer which wholly or partially stop the works of the Buyer, shipments contracted for shall be suspended or partially suspended as the case may require upon written or telegraphic notice to the Seller.

5. If the Seller shall fail to ship or the Buyer shall fail to accept the monthly shipments herein provided for and shall be excused for such failure under Articles "3" and "4" hereof, the other party at any time after the expiration of the first three months of the contract period may, by written notice to the party who has so failed to ship or accept, reduce the monthly tonnage thereafter to be shipped and accepted hereunder to an amount equal to the average of the monthly shipments for the three months preceding such notice.

6. The purchase of the coal specified herein is based upon present agreements with mine employees as to wages, and any increase or decrease in the cost of production of the coal shipped hereunder caused by changes in such wage agreements or by the imposition by State or Federal Statute of a direct tax on coal or the mining thereof or subsequent changes in the rate of such tax shall correspondingly increase or decrease said price of coal on any tonnage thereafter shipped hereunder and affected thereby.

7. The coal covered by this contract is to be used only in the plant or plants of the Buyer and is not to be sold or diverted by the Buyer to other purposes without the consent of the Seller.

8. Waiver by either party of any default by the other hereunder shall not be deemed a waiver by such party of any default by the other which may thereafter occur.

9. Notice sent by telegram or registered mail, addressed to the party to whom such notice is given, at the address of such party stated in this agreement, shall be deemed sufficient written notice in any case arising under this agreement.

10. No understandings, agreements or trade customs not expressly stated herein shall be binding on the parties in the interpretation or fulfillment hereof unless such understandings, agreements, or trade customs are reduced to writing and signed by the respective parties

In witness whereof, the parties hereto have caused this agreement to be executed in duplicate by their respective officers duly authorized the day and year first above written.

SOME GOOD ADVICE

By James Scotch

Numerous inquiries are made from time to time by correspondents in the columns of the technical press about steam engine trouble. Many of the letters sent to the press are so lacking in data that any "absent treatment" remedy suggested by readers must necessarily be only a guess at what the ailment is.

When a pound or knock suddenly develops in an engine some men seem to lose their engineering acumen, and in a sort of panic, try this, that, or the other thing, apparently hoping that if they try a lot of things they may be lucky enough to hit on the right one.

Often the right remedy is used and the pound removed. It is a fact that quite often the man who performed the operation is not aware of which change did the business because he had tried several at once, instead of testing one at a time.

Sometimes when a bad pound develops the engineer will try out a few remedies that he knows about, or has heard of. When he fails to get results he develops a feeling of helplessness, and writes to his favorite journal. Before he does this he should carefully study and consider the conditions and peculiarities of the pound, mentioning them in his letter. He should state what remedies he has tried out without success. As a rule any knock suddenly developing in an engine is of a simple nature, easy to cure if it can be located. It is sometimes mighty difficult to locate, and engineers even with a lifetime of experience may spend considerable time looking for the trouble. Engines are somewhat like humans in many ways. I once had charge of an engine which ran along month after month with little or no attention outside of oiling and cleaning. Suddenly it started to pound and search as we would it could not be placed. It was an old slide valve affair, slow in speed and heavy in build, one of the old timers which while none too economical in steam consumption, usually ran for 20 years or more without a cent for repairs outside of packing. It was so reliable that it was almost impossible to believe it could fail. I coaxed and petted it, examined bearings, bolts, nuts, etc., and everything seemed O.K., but just as soon as it was started the pounding returned. Ultimately a slight side slap was located at the eccentric. The knuckle joint on the eccentric rod had become a little worn and although there was only about 1-32 of an inch play, it was enough to cause the pound. Possibly and probably the knuckle joint had been loose for months, so why did not the pound start sooner? I imagine the engine got angry because the joint was not attended to. Regrinding and tightening the joint removed the pound.

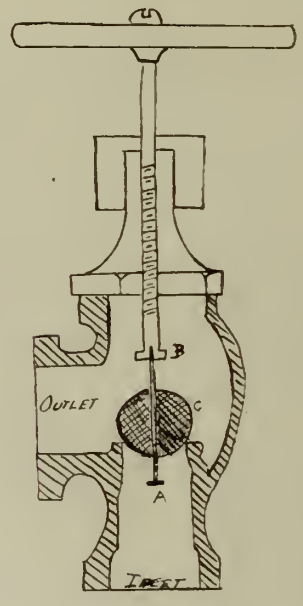
Another time a nasty pound started in an "Ideal" high speed engine direct connected to a D.C. generator. After considerable testing a small bolt or set screw on the flywheel governor pin was found to be loose. Nothing else was wrong.

Another time such a set screw loosened up but no pound started. What did happen was that the operation of the generator was affected, because the engine governor was not working properly.

My object in writing this is to impress on the minds of men not used to writing for the press to get the proper data as near as possible before asking mail order treatment for engine trouble.

A USE FOR OLD VALVES.

Hundreds of angle and globe valves are discarded as junk when they would supply months of useful service on cold water on gas mains. The accompanying sketch shows a method by which this can be done. This valve takes the place or answers the purpose of a check as well as a stop. A hard rubber ball, C, is used instead of the disc, the disc and holder are removed from the stem, and



VALVE FITTED WITH RUBBER.

a hole drilled and threaded at B to take the rod A. A hole is made through the ball just big enough to allow the ball to move on the rod freely. When the valve is closed the stern end at B makes a tight joint. When the valve is open, the stop at A holds the ball up. To act as a check valve, the stem is placed in the position shown. One defect as a check valve is that it will not be absolutely tight, as a certain leakage will escape through the rod hole. However, there are many temporary jobs where this made-over valve would answer nearly as well as a new one.

A WORD FROM QUEBEC

Editor Power House:

I am the holder of a second-class certificate in the Province of Ontario and also in the Province of Quebec. I have often felt like going back to Ontario, thinking stationary engineering would b much better since the graded certificat came into force. After reading an ac vertisement in the Montreal Star fc March 31st, I have come to the conclusio that I am better off in the Province c Quebec. The ad is as follows: Wanted- Fireman holding second-class certificat Apply Canadian General Electric Cc Peterborough, Ont."

I hope the chief engineer of the Can dian General Electric found a secon class man to handle the scoop. I wond how he would like to have seen the sar ad a few years ago when he carried second-class certificate. I consider th an insult to any man holding a secon class certificate. Is it possible that the are so many second-class engineers Ontario that they have to go back firing, a job they have presumab climbed from years ago?—W. P. R Montreal.

ANNOUNCEMENT.

Louis T. Klauder has resigned fro the Philadelphia Rapid Transit Compar as construction engineer and will ent the consulting engineering field. He a graduate of the Williamson Scho and of the Drexel Institute in mechan cal and electrical engineering.

Mr. Klauder entered the enginee ing department of the Pennsylvan Iron Works Company in 1901. He b came associated with the Philadelph Rapid Transit Company in 1905, wi which company he has occupied in tu positions of draftsman, chief draftsma assistant engineer and construction e gineer, in charge of plant design a construction. In his consulting work l will specialize in that field of enginee ing in which he has been most acti and progressive.

Like many of the more successful e gineers, he has kept in close contact wi the advances of his profession throu membership in major engineering soci ties with which his activities are associa ed, being a member of the Americ Society of Mechanical Engineers, Ame can Institute of Electrical Engineers, a the Engineers' Club of Philadelphia.

Through the organization of an offi as unusual as it is distinctive, Mr. Kla der is already directing a number municipal industrial power plant develo ments, among which are the new wat and lighting plants of the city of Jam town, New York.

On and after April 1st, 1921, Mr. E. Jones will be in charge of the N York office of the Homestead Val Manufacturing Co., at No. 242 Lafayet street, New York City, where he w carry a large and complete stock "Homestead" Quarter-turn Valves a "Hovalco" Valves, and be in readine to give prompt service to all custome in this district.

FAIRBANKS-MORSE
BALL-BEARING MOTORS
Give Uninterrupted Service

The absolute dependability of Fairbanks-Morse Motors accounts for their extensive use in Power Houses throughout the world.

These ball-bearing motors have set a new high efficiency standard in saving power. The bearings, packed in grease, reduce friction and assure continuous operation.

The one-piece solid rotor winding with cast-on end rings, insures greatest electrical efficiency by preventing arcing due to loose rivets or screws, and eliminates costly repair bills.

You should not buy or specify electric motors until you have thoroughly investigated Fairbanks - Morse Ball-Bearing Motors. Write our nearest branch for any information you need.

The Toronto Board of Control, acting on the recommendation of the property commissioner, will oppose the application to the legislature for a bill which proposes to exclude brick yards from the operation of the smoke by-law.

Two gasoline engines of 200 horsepower each have been installed in the pumping station of the Pembroke waterworks, in conjunction with two De Laval centrifugal pumps, having a capacity of 800 gallons per minute. The installation was made by the Turbine Equipment Co. of Toronto.

The Montreal Chambre de Commerce has been considering the advantages that would follow the building of a tunnel under the Champ de Mars and Jacques Cartier Square, for the purpose of relieving the congestion that frequently occurs in this vicinity on market days and when traffic to and from the harbor front is excessive. No definite action has been taken but the project has been laid before the Administrative Commission.

Auto Supplies Co., Ltd. Incorporators: Henry Howard Shaver, barrister-at-law; Alexander Findlay Boyle, automobile builder; and others, all of Toronto. Capital $150,000, divided into 1,500 shares of $100 each. Head office Toronto.

The Imperial Oil Co., Ltd., are planning to erect a two-story, fireproof office, a large two-story fireproof garage, boiler and pump house and a plant for the repair and care of barrels, at Brandon, Man. Two ten-thousand barrel tanks will also be installed and the necessary lubricating storage plants. It is expected construction will begin in the spring and be completed in the fall of 1921.

To Make Matches. — Sir Alexander Maguire and his brother Dr. D. P. Maguire, who have been in Montreal at the Ritz-Carlton Hotel in connection with the plans for the erection of a match factory plant to be operated by the British firm of Maguire, Paterson and Palmer, Limited, have left for New York, where they will embark on the Olympic for Southampton. They expect to return in about three weeks to complete all details of their plans.

Erecting Big Plant.—Announcement is made of the sale in Toronto of five acres of land at the corner of Hanson Street and Coxwell Avenue, where there is at present a Grand Trunk Railway siding. Plans and specifications have been prepared for the erection of a modern daylight plant of the best brick and mill type construction. The cost of the building will be in the neighborhood of half a million dollars. The main building will be 500 feet long and 80 feet wide. Upon completion three companies will commence operations in the buildings: Crouse-Hinds Company of Canada; Harvey-Hubbell, and the Hubbell-Mack Machine Screw Company. The new plant is not expected to commence operations until November 1, 1921.

The Engineering Equipment Company, Limited, sales engineers, dealing in mining, contracting and industrial machinery and supplies, have opened offices at 263 St. James Street, Montreal. The company has secured the exclusive selling rights for many leading lines of such equipment from firms in the United States and Great Britain, as well as many in Canada. The officers of the new company are: president, Norman M. Campbell, late general sales manager of the Canadian Ingersoll Rand Company; vice-presidents, Samuel Seaver, formerly Canadian sales manager for Sullivan Machinery Company and Canadian Rock Drill Company of Toronto; and Fred H. McKechnie, of McKechnie & McLaren, sales engineers of Montreal. Percival J. Woolf, late manager of the General Electric Company at Duluth, is the secretary-treasurer.

Making Radiation Usable

All who specify and install radiation are agreed upon one point: radiators cannot do their work when they are choked up with air and water.

The two curves are from actual laboratory tests and the same radiator, fitted with two kinds of radiator traps—one of which was the Dunham Radiator Trap—the trap that has been making radiators practically 100% hot since 1903.

You know which trap you would prefer. So would the man who pays the bill for the radiation which he rightfully expects will keep every room warm.

Making radiation usable is as commendable as the conservation of coal.

EMPLOYMENT DESIRED

ENGINEER-MILLWRIGHT, 3rd CLASS, MARried. Wants position. References. Apply Box 201, Power House. (pfh)

MACHINIST—WITH DRAUGHTING EXPERIence, wants work of any kind. N. Ryckman, No. 174372. 5 Foxley St., Toronto. Phone Parkdale 3254w. Mention "Power House." (pfh)

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House. (pfh)

A Real Service To Engineers

Mr. John H. Forsyth, Chief Engineer of the DeLaval Co., Peterboro, says of POWER HOUSE:

"The whole thing can be said in a few words—'Power House' delivers the goods and no engineer who has the interests of himself and his employer at heart should be without it."

Many men have paid thousands of dollars to get necessary information that would contribute to their success. You, as an engineer, or power plant employee in any capacity whatsoever, will be interested in this fact, that your expenditure for knowledge need not be excessive. You can have it fresh, twice a month, twenty-four times a year, for two dollars. For "POWER HOUSE," the Power Plant Journal of Canada, positively delivers the goods—edited by Canadian men with the Canadian viewpoint well in mind. Do you know that hundreds of engineers have told the publishers that POWER HOUSE has been frequently of inestimable value to them, solving their problems, guiding their vision, steadying their attitude, and qualifying them for bigger jobs, increasing their earning power; in a word "POWER HOUSE" shortens the way to success in a very practical and continuous way to the man who really cares and is willing to come across and take what "POWER HOUSE" has to offer.

POWER HOUSE,
The MacLean Publishing Co., Ltd.,
143 University Ave., Toronto.

Please enter my name as a regular subscriber to the POWER HOUSE Journal, commencing at once. I am enclosing $2 to pay for my subscription for the first year. (Write address plainly.)

NON-CORROSIVE CYLINDER OIL

MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 242-244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

Chimney Repair Work

Does your chimney need repairing? Experienced chimney foreman and expert repair man is open for engagements. Put your problems up to me. Rates reasonable.
Box 203, Power House.

EQUIPMENT

STEAM ENGINES, BOILERS, HEATING tanks, stacks, pumps and condensers, transmission and elevating machinery, safes, vaults and vault doors; catalogue and specifications sent on request. Apply, mentioning "Power House," to Goldie & McCulloch Co., Ltd., Galt, Ont.

PORTABLE BOILERS—LOCOMOTIVE TYPE on wheels, each 15 horsepower, with engine mounted on boilers; can get Government certificates for 90 and 100 pounds working pressure cheap; also 40 horsepower, high speed Leonard automatic engine. Apply, mentioning "Power House," to Henry Engineering Co., 71 Bay St., Toronto.

BOILERS AND POWER PLANT EQUIPMENT bought by the Henry Engineering Company (Henry-Rumgay-McBryde), 71 Bay St., Toronto. Mention "Power House."

Out of a dozen men who are asked to guess the temperature of anything, not one will be able to give it accurately.

As an engineer, you know the great importance of maintaining correct feed-water and flue-gas temperatures. You will readily recognize, therefore, the great value of receiving written records of these temperatures by installing

Columbia
Recording Thermometers

You will then know **exactly** what your temperature conditions are every minute, day and night. They give an absolutely accurate record of the slightest temperature variation—an indelible inscription on a renewable chart, which places in your hands valuable information that enables you to secure perfect temperature control.

Failure to maintain a stipulated temperature, through carelessness or ignorance, can be instantly checked by the use of this sensitive but rugged instrument.

Scientifically constructed and rigidly inspected, Columbia Recording Thermometers are guaranteed to be accurate and infallible. For all temperatures up to 1000° F.

Shall we send you our catalog H-33?

Worthington builds every type of boiler feed pump

POWER plant engineers and managers benefit by the Worthington policy of building every type in each of its lines of equipment.

Take for instance the Worthington boiler feed line. Steam pumps include single and duplex, horizontal and vertical types in pot valve plunger and standard piston models for all ranges of pressure. Similarly, Worthington centrifugal pumps are built in patterns to meet the varying conditions of temperature and pressure found in boiler feed work.

This policy of manufacturing every type of a given equipment assures to the buyer impartial advice on his selection.

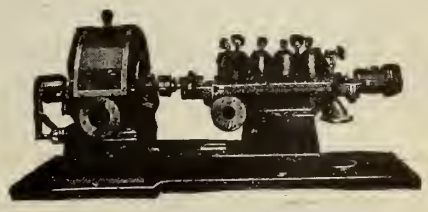
B 31



Double Suction Turbine Pump, Boiler Feed Pattern

Centrifugal pumps often become steam bound while handling hot water. Under such conditions, the rotating element of the average pump may seize at close clearance points. Worthington double suction centrifugal boiler feeder is equipped with a special floating sealing ring which prevents this binding.

"KYMBALA"

AN IDEAL JOINTING

IT would be folly to contend that no further improvement is possible in jointing material, but "Kymbala," manufactured from Blue or South African Asbestos Fibre, is now widely admitted to be a great improvement on all Jointings hitherto manufactured. Its advantages may be summed up as follows:

PURITY.—Blue Asbestos contains only 4% impurities against 15% in the best White Asbestos Fibre.

TOUGHNESS.—Blue Asbestos is of double the tensile strength to White Asbestos.

PRESSURE-RESISTANCE. — Blue Asbestos Fibre is admittedly the hardest and most resilient Asbestos Fibre extant, besides being water and steam-resisting, and can absolutely be relied upon not to "blow out."

DURABILITY.—Owing to its great purity, strength and pressure-resistance, it has proved to last easily more than double the time of other high grade jointing, thus considerably reducing stoppages, labour and material.

WEIGHT.—"Kymbala" is the lightest Jointing, hence means a reduction in cost. Put it to the test, you'll find it the best in every way.

Samples for trial will be supplied on application to the sole Manufacturer

"Belting trouble ends where D.K.McLaren's Belting begins"

"Cheap" Belting

The flawless back leather of selected hides, tanned by the Genuine British Oak Process—made so pliable, so tough and durable as to be practically slipless, stretchless and unbreakable—this is D. K. McLaren's Leather Belting. Wouldn't you consider it "cheap" at almost any price?

And yet we have made it possible to manufacture belting such as this and sell it at prices which are as low as any on the market—quality considered.
